Vegetable-feeding animals need a wide visual range for protection against their carnivorous foes. Accordingly, we find that in them vision is extensively panoramic, admitting of considerable range posteriorly, while their binocular vision is correspondingly limited. In the rabbit and the hare, with little or no binocular vision the non-decussating (direct) optic fibres are very few in number. In the ungulates the binocular field is somewhat wider: in the horse, about one-sixth of the fibres are direct.

In the carnivora accurate near vision is needed for seizing the prey: hence they have a wide range of binocular vision and a proportional number of direct optic fibres. Monkeys, which seize objects with their hands and subject them to close scrutiny, are endowed with a high degree of stereoscopic vision, and the number of direct optic fibres is correspondingly great. In the anthropoid apes the behaviour of the optic fibres as regards decussation is much the same as in man.

The visual field.—It is necessary to remember that the movements of the eyes have little or no appreciable effect upon the limits of the visual field. Those remain much the same when the head is maintained in one position, no matter in what direction the eyes are moved. The object of eye-movements is not to extend the field in different directions, but to bring particular portions of it within the macular range.

The visual field of each eye extends more

towards the temporal than the nasal side (Fig. 8), being limited in the latter direction by the projecting nose. It is normally more extensive in some than in others. For example, the retina does not extend so far forward in myopic as in

FIG. 8.—The outer circles represent the perimetric chart. The inner interrupted lines represent the boundaries of the two visual fields. It will be observed that the temporal portion of the field is more extensive than the nasal.

normal eyes, and this causes a corresponding reduction of the visual field. The larger the pupil, the larger the field. The field may also be greatly reduced in debilitated states of health.

When an object is slowly introduced into the periphery of the field its presence, though not its exact form, is perceived before its colour. The colour field is thus less extensive than the actual field. Nor is the field the same for all colours: the order in which colours are normally perceived from without inwards is as follows—white, blue yellow, orange, red, green, violet. On the other hand, the peripheral portions of the retina are much less sensitive to form than to colour. The form of letters, *e.g.*, can only be perceived when they are imaged on the central portions of the retina.

In testing the visual field the upper lid should be lifted with the finger. Accurately to test the visual fields of the two eyes a perimeter is required, but a rough test may be made in either of the following ways:

The patient and the observer sit down opposite each other but in close proximity, and with their eyes on the same level. Thus each covers a *vis-a-vis* eye. The fields of the uncovered eyes ought then to correspond approximately, for the bridge of the nose which limits the field on one side limits it on the same side in each case. The observer now introduces his hand at various points in the periphery of the field, rapidly moving the fingers all the time, but taking care to keep them in the vertico-transverse plane midway between his own eyes and those of the patient. If the fields are normal both persons should see the fingers at about the same time. The colour fields and the central region of the field can also be tested in this way. In employing the test care should be taken that the incidence of light is the same for both observer and patient.

In the second test method one eye of the patient is covered, and he is asked to fix his uncovered eye upon a spot marked upon a dark surface, such as a blackboard, placed at a distance of about eight inches. A piece of white marking chalk is then brought into the visual field from various points of the periphery, and those at which it is first perceived are marked off on the board and joined. The colour field can similarly be tested, as well as the central areas of the field.

(To be continued.)

THE SURGICAL TREATMENT OF SARCOMA OF THE LONG BONES (a)

By SIR FREDERIC EVE, F.R.C.S.,

Senior Surgeon to the London Hospital.

FOR purposes of treatment sarcomata of the long bones fall into three groups:—

- (1) Periosteal sarcoma.
- (2) Central sarcomata composed of round and spindle cells.
- (3) Myeloma (myeloid sarcoma).

(1) *Periosteal Sarcoma*.—The periosteal sarcomata spread locally along the periosteum, endosteally through the medulla and also along the muscles attached to the affected bone. Extension into veins was so early that in many cases, especially in sarcoma of the femur and humerus, metastases were present when the patient first came under observation. Sarcomata of these bones frequently involved the axillary and femoral glands respectively.

Amputation in periosteal sarcoma must remove the affected bone in its entirety, and if possible the whole or a considerable part of the length of any muscles attached in the neighbourhood of the tumour.

In periosteal sarcoma of the humerus Berger's operation was usually necessary.

Notwithstanding the unsatisfactory results of treatment of periosteal sarcoma of the femur, he thought the patient should be given the remote chance afforded by amputation of the hip joint. With modern methods of combating shock the immediate danger of the operation was slight. The speaker had performed eleven consecutive amputations of the hip joint without a death.

Periosteal sarcoma of the upper third of the leg and of the fore-arm should be treated by amputation at the lower third of the thigh and humerus respectively.

(2) *Central Sarcomata Composed of Round, Spindle or Mixed Cells*.—The lower degree of malignancy of these tumours must be ascribed to their being surrounded by a capsule of bone, but in many instances there was a wide infiltration of the medulla and the osseous capsule had been broken through. In the latter case they should be treated on the same lines as periosteal sarcomata. Otherwise it would appear safe to amputate through the affected bone some distance above the disease. Cases were quoted indicating that in some examples of central spindle celled sarcoma resection might be resorted to.

(3) *Myeloma (Myeloid Sarcoma)*.—In most situations these tumours exhibited a purely local malignancy, but this did not appear to be always true of myelomata of the femur and humerus; and cases were quoted of myelomata of these bones in which metastases occurred after amputation. The statistics of the London Hospital showed that all cases that could be traced of myeloma treated by operation (during the last ten years) were well for periods varying from one and a half to eight years; but all those of the humerus and femur were treated by amputation. Four cases involving the upper ends of the tibia and fibula respectively were treated by resection or erosion and none recurred.

The speaker was of opinion that the higher malignancy of myeloma of the femur and humerus depended rather on the seat of disease than on the structure of the tumour. The nearer the body the greater the malignancy would appear to be true of myelomata as well as of periosteal sarcomata.

Myelomata might be treated by erosion, resection

(a) Abstract of paper read in the Surgical Section of the Royal Society of Medicine on Tuesday, November 12th, 1912.

or amputation, according to the seat and extent of the disease; but conservative treatment was much less likely to succeed in myeloma of the humerus and femur.

A surgeon about to operate for sarcoma, especially if it were a central tumour, should have a microscopist in attendance for the purpose of making a fresh section; and in some cases it might be advisable to postpone operation for a careful examination.

The recent advances in the surgery of transplantation of bones, cartilage, and even of joints, had opened up a new field for the treatment of myelomata in selected cases. A portion of bone from the same individual was utilised (autoplasty), or from an amputated limb or a corpse (homoplasty). In the first category the fibula had been widely used for grafting, both in resections of the upper end of the tibia and also of a bone at a distance such as the ulna. If fresh bone were used the periosteum should be preserved, as new bone formed beneath it. He showed a patient in which the fibula had been used for bolting the bones together after resection of the upper third of the tibia for myeloma with a good result.

A case was quoted in which Kausch had successfully employed a graft of bone from a corpse to replace the upper end of the tibia removed for myeloma; and cases in which Küttner had successfully used corresponding portions of bones from corpses to replace in two instances the upper third of the femur and in another instance the upper end of the tibia. It was quite evident that bone grafting had a future before it in selected cases.

The speaker had been especially asked to make some remarks on the treatments of sarcoma with Coley's fluid. After detailing Coley's results and views as regarding the treatment of sarcoma of the long bones with his fluid he quoted the results obtained at the London Hospital. In no instance had any improvement occurred in periosteal sarcoma of the long bones. As regards the prevention of recurrence by Coley's fluid he stated that in the only three of his own cases in which a striking diminution of the tumour had occurred under the toxins, and subsequently local removal had been performed, in two cases local recurrence took place and in one metastasis.

It was undeniable that a certain number of sarcomata disappeared, or were profoundly influenced by the toxins, but we had no means of determining what proportion this was to the total number treated. He believed that it was only a small proportion.

His present attitude was unfavourable to the employment of Coley's fluid in any case of operable sarcoma, and even as a prophylactic against recurrence.

PERFORATED DUODENAL ULCER (a)

By JOHN W. STRUTHERS, M.B., B.Ch.,
F.R.C.S.ED.,

Surgeon to the Leith Hospital; Lecturer on Surgery in the School of Medicine of the Royal Colleges of Edinburgh.

THE paper was based on a study of twenty-seven cases. The cases occurred at all ages, but only one of the series was a woman.

Seventeen cases gave a history of previous aggravated dyspepsia. Vomiting was rare. In only one case was there a history of melæna. In some cases pain occurred almost immediately after the ingestion of food. Hunger pain is not necessarily associated with duodenal ulcer. Five patients had suffered from occasional dyspepsia, but any slight symptoms they had would not have been sufficient

to justify a diagnosis of duodenal ulcer at all. A third group of cases had no previous history of digestive discomfort. Too much reliance must not, therefore, be placed upon the previous history.

There is no premonitory sign or symptom which indicates that perforation is imminent, and there is no direct cause for its occurrence. After the perforation has occurred, pain, muscular resistance and general abdominal tenderness often make diagnosis easy. By the time the patient is seen by the surgeon, however, the period of reaction has set in and diagnosis may be difficult. Pain may have disappeared either spontaneously or as the result of sedative medicines, and in some cases the pain may be referred to the right iliac fossa. Such cases are apt to be regarded as appendicitis, but suspicion may be aroused by the widespread muscular resistance, and by the fact that the temperature and pulse are not markedly raised. In some cases the differentiation may be impossible, and in such cases it was the author's custom to open the abdomen through the right rectus muscle, just below the umbilicus, and explore the appendix, and then, if necessary, extend the incision upwards. In muscular subjects with strongly contracted muscles it is important to have the muscles thoroughly relaxed, and the anaesthesia must be as deep as is consistent with safety. Chloroform alone has been preferred. The previous use of morphia seemed to diminish the activity of the respiratory centre.

In all cases the perforation was found on the anterior aspect of the duodenum within an inch or an inch and a-half of the pylorus. Its size varied greatly. The wall of the duodenum was usually cedematous and friable. Solid material was not found in the peritoneal cavity, except in one case where perforation followed shortly after the administration of a bismuth meal. The copious peritoneal exudate prevents the making of any accurate estimate of the amount of fluid escape. The ulcer is closed by interrupted sutures of thick catgut introduced at right angles to the long axis of the pyloro-duodenal junction. Number 2 or 3 catgut, not chromicised, makes the best suture. When the patient is desperately ill the operation is finished by swabbing out excess of fluid, inserting a large tube into the pouch of Douglas and closing the upper wound. But when the patient's condition justifies it, a posterior gastro-enterostomy is performed. Closure of the perforation does nothing to alter the conditions which have given rise to the ulcer and nothing to prevent relapse or recurrence of symptoms, and the necessary narrowing of the duodenum must tend to prevent the healing of the old ulcer or to increase the liability to the formation of a new one. The puckering and irritation of the stitches probably interfere with the proper action of the pylorus. In seventeen of the present series posterior gastro-enterostomy was performed, and all of them did well. Out of three cases in which gastro-enterostomy was not done two have symptoms which suggest the presence of an ulcer, while the third is free from dyspepsia as he was before operation. Washing out the peritoneum is not necessary, and probably harmful. A supra-pubic drain is sufficient to carry away any excess of fluid which may be poured out.

Results.—Two of the cases were moribund when seen. The remaining twenty-five were operated upon, and twenty recovered. These owe their recovery to early operation.

The conclusions reached were:—

1. That duodenal ulcer may be present, and go on to perforation without giving rise to characteristic symptoms before perforation.
2. There are no symptoms which may justly be termed premonitory of perforation.
3. After perforation diagnosis may be difficult,

(a) Paper read before the Edinburgh Medico-Chirurgical Society November 6th, 1912, Mr. J. M. Cotterill in the Chair.

either from the pain being referred to the region of the appendix or from early and marked abatement of the severity of the symptoms.

4. Catgut may safely be used for purposes of suture, and is preferable to silk for this purpose.

5. Gastro-enterostomy should be done at the operation for closing the ulcer when the patient's condition permits of it, since this measure promotes immediate recovery and lessens the tendency to recurrence of ulceration.

SHOCK. (a)

By F. G. CROOKSHANK, M.D.LOND., M.R.C.P.,
Assistant Physician, the Belgrave Hospital for Children, etc.

THE discussion and understanding of shock, although of paramount importance to the clinician, the physiologist, and the lawyer, is involved in much obscurity. Perhaps it would be well to avoid, at any rate, terminological confusion by setting on one side, as distinct from shock, the condition known as "collapse." By "collapse" we mean that sum of bodily states which is associated with loss or draining of the vital fluids, as in hæmorrhage or cholera. Shock remains as the sum of conditions obtaining when the reaction by the nervous systems to afferent impulses is incompatible with the usual performance of vital functions; so that the patient may die without the necessary coincidence of any obvious lesion in itself inconsistent with life. But, of course, shock and collapse may coexist.

We cannot hope to estimate the intensity of the afferent impulses that is requisite to destroy life by shock; for, as Mr. Tyrrell Gray has said, we have to reckon with the shock value of the individual. Probably this shock value is a physiological "function," but there are racial values, as well as individual values. In great measure these depend on the state of the internal secretions or their balance. Thus, the hyperthyroid Bengalee has a higher shock value than the negro, and the lively Gaul is more easily perturbed than the phlegmatic Teuton. Still, the shock value of an individual varies from time to time, and different parts of the body have different shock values. A tap below the belt may wind a man on whose thorax I could hammer without causing distress; and there are other elements—to wit, that of unpreparedness. A false step in the dark may momentarily shake the nerves of a man who will take the spills of a day's hunting without turning a hair; and the late Mr. Dent pointed out how a policeman, suddenly injured when on duty in a street brawl, will suffer more severely from shock than a soldier wounded in action.

Again, the trauma may be what is called "psychical," as when a piece of bad news is communicated, or there is a sudden and terrifying sight; although there is always a physical process underlying psychical impression. When these factors are considered, it must be agreed that, unless there be definite simulation, we have little justification for aspersing one who complains of serious perturbations on an occasion that may seem to us trivial. Many people have, indeed, as we say, died of simple fright.

I spoke just now of the nervous systems designedly; for we have not one, but three, nervous systems. We have the cerebro-spinal nervous system, the sympathetic nervous system, and also the co-ordination of parts of these two into a third organisation—the autonomic nervous system. If, for the sake of legal members, I may hazard an illustration, I would say that just so in this country we have a fairly stable and organised aristocracy and a less coherent democracy; though the system on which the stability of the constitution depends is that formed by the co-operation of a part of the aristocracy, and a part of the commonalty. And, seemingly, in shock the maintenance of the functional integrity of the autonomic system is seriously compromised. It is certainly true that what doctors call "shock" (meaning thereby the consequences of a shock) is, in part,

a defensive reaction of the autonomic nervous system against assault that has been committed. It fails of its purpose at times, no doubt, and may even be too intense for the safety of the organism. But the fact remains that, as Crile has pointed out, the shock mechanism is one forged many generations ago in the history of the race, when some apparatus was necessary to secure instant preparation for flight or withdrawal on occasion of danger.

Poke a snail with a straw, and see it draw in its horns. Such are the beginnings of the complexes of shock and of traumatic neurasthenia which so admirably contribute to the support of our twin professions. But just as a rifle may have too light a pull, so may the shock reaction be overdone, to the disadvantage of the organism.

It is perhaps somewhat unfortunate that, owing to the possibly excessive attention paid to experimental work of late years, shock, to the minds of many medical men, has come to mean an affair of blood-pressure curves, and what not, that can be best investigated in dogs and on rabbits. And so some of the shock effects that can hardly be investigated save by observations on human beings have become a little discredited, and are almost treated as if they had no existence, or, at any rate, no right to be mentioned in polite professional society. It is to some of these shock effects, and particularly to those indicated by the term "delayed shock," once in some clinical favour, but now a little in the shade, that I propose to refer.

If we have to state the most intense form of shock, we at once think of those cases of sudden death, where there is no precedent disease, that are brought about by events which produce no obvious lesion. Such deaths happen when there is sudden immersion in water, and the individual dies without having time to drown. Other examples are narrated by Brouardel in his book, wherein he, following Brown-Séquard, speaks of them as deaths from inhibition. Let me give you an instance.

Last summer a Sikh was cycling through a London street. He had a side-slip when opposite a hospital. He was at once taken in, but no injury was found save a dislocated thumb, which was reduced. He turned to leave the hospital, and died on the doorstep. At the *post-mortem* neither injury nor disease was found. When, however, shock falls short of immediate death production, there may be a very serious condition lasting some twenty-four hours or so, which may be terminated by death or may end in gradual recovery. This is the common kind of shock, from which we say people suffer after operation or serious injury. But there is a group of serious cases in which, after the infliction of some trauma, the subject displays emotional perturbation, rallies, seems to be doing well, and yet ultimately develops symptoms which may be indifferently severe or may terminate in death.

The cases from which there is recovery sometimes pass as "traumatic neurasthenia," in which, as all know, a definite latent period elapses between the symptoms immediately displayed and those that "come on" later, and give us so much occasion for professional activity. The cases in which, after a latent period that may be long or short, grave and even fatal consequences ensue, are those to which I now refer as cases of "delayed shock," using a term that is, or was, consecrated by use. Common to both traumatic neurasthenia and delayed shock are unexpectedness of the trauma, and high psychical, rather than physical, value of the causative incident.

The prolonged anxiety and stress of shipwreck is not so effective in producing traumatic neurasthenia or delayed shock as in a railway collision; or a prank played on a kitchenmaid with a turnip, a clothes-prop, and a candle.

Now, it is not an unreasonable induction that the symptoms which follow the latent interval are perhaps due to the exhaustion of certain mechanisms in combating the immediate effects of the physical or psychical trauma. And, indeed, years ago Mr. Furneaux Jordan very acutely pointed out that many of the immediate manifestations of what we call

"shock" are really efforts of the organism to combat the effect of the trauma. When we have a sudden fright, if taken off our guard, we turn pale. The blood is diverted from the skin, where it is not needed, to the heart and lungs, so that these organs are well supplied for the immediate flight prompted by our ancestral origins.

Now, the experimental work of Cannon and his associates seems to prove that when animals have been subjected to injury, or deliberately frightened to death, the adrenal system (a part of the mechanism that manages the blood-distribution) may be so completely exhausted by its efforts that it becomes bankrupt, and death ensues. In these experiments we seem to see the physiological explanation of the phenomena of "delayed shock" in human beings. Cases of delayed shock are not very uncommon, but they are often masked. We all know how usual it is for an aged person to die a week or two after a slight fall that has involved fracture of the femur. This is "delayed shock." It escapes recognition as such only because there is, what sounds formidable, a fracture of the thigh. Yet a fracture of the thigh is itself a trivial affair so far as life is concerned. It is true that sometimes a low kind of pneumonia ensues, but not always; and even when it does, there is a valid explanation. At any rate, the pneumonia itself is seldom so severe as necessarily to interfere with life. Again, after burns, death from delayed shock is not infrequent even when no vital organ has been implicated and there is little sepsis.

The point that I am anxious to establish is this: that when death occurs ten days or so after trauma, we should not hesitate to ascribe death to the "accident" merely because there has not been present such a totally irrelevant lesion as a fracture of the thigh or an extensive scald. I do not say that such deaths are very common, for obviously there usually is a lesion; but they do occur. I have met with several, and have had the opportunity of inquiring into others. Many have been recorded in forgotten papers; but the modern text-books ignore them in most remarkable fashion, and even so erudite a compilation as Mr. Knocker's makes no mention of their happening. Though they present, as is only natural, points of individual difference, there are not a few symptoms from which we can construct a common denominator. There is usually immediate manifestation of some psychological agitation; but this may pass off. There is a longer or shorter period in which the patient may seem to be suffering hardly at all; and there are indications of interference with the visceral functions. The blood-pressure is affected, and the heart tends to dilate, for it loses tone; the urine is scanty; the bowels are obstinately constipated; flatulence and eructations are common; and there is a good deal of shortness of breath. As it may be the respiratory, the cardiac, the gastric, the intestinal, or other symptoms, that notably attract the doctor's attention, so, if death occurs, it is ascribed to congestion of the lungs, to heart failure, to pressure of the stomach on the heart, to stoppage of the bowels, or even to suppression of urine. (a) Sometimes the flatulence, constipation, and distension are so marked that operation is proposed and carried out; but no condition is found within the surgeon's ambit.

When after trauma there are continuing hysterics, the patient will probably win through with little physical damage. When the early psychological disturbances have play, but are controlled, traumatic neurasthenia, or the more marked type of "delayed shock," may ensue. But sometimes there is no initial hysteria; the subject displays a peculiar apathy, and death is pretty sure to follow.

You will all remember how when—

"Home they brought her warrior dead;

She never spoke nor uttered a cry;

All the maidens watching said:

'She must weep, or she will die.'

In such cases the autonomic nervous system is thoroughly disorganised, probably by inhibition from above.

(a) In a measure the "shock mechanism" may be concerned in some "Obstructive" suppressions of urine. The relation of Graves's disease to shock should not be forgotten.

The connections at the synapses are broken, and unless contact is re-established death may ensue.

The warrior's lady had her fount of tears dried up, and probably she was obstinately constipated and passed no water; when her autonomic nervous system got to work again not only the tears, but other secretions were doubtless abundantly established, with excellent results.

Mr. Clinton Dent once related how, many years ago at St. George's Hospital a water-tank burst through a ceiling and the floor below, carrying with it in its career a bed in which was a woman convalescent from some unimportant affection. This woman, in spite of her precipitate descent to the lower ward, sustained no overt injury save a trifling scalp wound. But she passed into a curiously apathetic condition, like that exhibited by some patients who have been burnt. She was seen by the late Mr. Cæsar Hawkins, who said that, though he could give no reason for his opinion, yet his experience taught him that she would die. She did die, about three weeks after the accident, and at the *post-mortem* no lesion was discovered. Mr. Page recorded the case of a girl who was shaken in a railway accident. She was hysterical at the time, but rallied, then took to her bed and died, without any obvious reason, in about five weeks. Sir Samuel Wilks narrated other cases of the same sort.

Mr. Turner several years ago reported the case of a man who fell when crossing a railway track, and broke his leg. That same night he developed retention of urine, absolute constipation, and abdominal distension. In two days he was lying in bed "like a ball." He had no peritonitis or other indication of visceral injury. But he died on the tenth day. It is true that before he died some pneumonia developed, but, as Mr. Turner says in a pregnant phrase, this shows that the shock had affected other organs than the bowels.

Cases of what is called "traumatic pneumonia" are not very uncommon, and one—the case of Etherington—is a legal classic.

But the usual explanation given is that the accident or injury in some mysterious way lowers the patient's vitality, and renders him or her more susceptible to the pathogenic growth in the lungs of the pneumococcus, which is, of course, a very usual denizen of the mouth. This mysterious lowering of vitality seems to me a phrase which explains nothing.

It has some appearance of plausibility when the pneumonia follows a blow on the chest, but it loses force when we consider the case of a man with a broken leg; so that it is then usual to suggest that the pneumonia is hypostatic, the result of congestion of the lung from confinement to bed. Mr. Turner's case forces us to seek some other explanation, and his expression, that the pneumonia showed that the shock had affected other organs than the bowels, carries us some way towards an understanding.

Everyone knows that, in spite of the jeers of therapeutic nihilists, a poultice or a mustard-plaster applied to the skin does affect the functional state of deep-seated organs. And we know that disease processes in certain organs give rise to pain in correlated skin areas. Now, whereas till lately the notion of what is called "counter-irritation" had been a little discredited, the phenomenon, for instance, of abdominal pain and tenderness in pneumonia does show us that there is an active connection between the cutaneous nerves and the viscera, and no longer renders it foolish to think that an active poulticing may, through the nerves controlling the distribution of blood to an organ, so affect the vascular state of that organ as to favourably influence disease processes.

And we have physiological justification for assuming or believing that, let us say, the application of cold to the skin may, under certain circumstances, so affect the state of deep viscera, in respect of the local circulation of blood therein, as to pave the way for the establishment of an active microbic inflammation.

We, know, too, that normally certain skin areas are correlated with certain viscera for good or for evil. But we have to reckon with the phenomenon of irradiation, whereby the effects of an intense nerve impression spread to units of the autonomic nervous system

(which is, indeed, a series of segments or units) other than the proper one. You may in some buildings see a telephone switchboard so arranged that different persons can be called, or can call, independently. Such is the normal arrangement of the autonomic system, whereby skin areas can call up visceral areas, and *vice versa*. But an arrangement may be made so that if a call of fire is received at the office a special switch can be thrown over, and the various instruments can be simultaneously rung. If the operator is a fool, this is done unnecessarily.

And in shock something of this sort seems to occur; so that we can see how it is that, as in Mr. Turner's case and others, a physical and psychological trauma may, given certain conditions, adversely affect the vascular state not only of the bowels, but the lungs. Neuhof, an American physician, has lately paid particular attention to this mechanism for the occasional production of pneumonia. He calls some such cases of pneumonia "vagus pneumonias," for physiological reasons.

A case of great legal and medical importance came under my notice a few months ago. The subject was a man well known to me by repute—healthy, sober and active. His age was 49. On the evening of November 14th last he left the house of a friend to walk to the station. In passing through the grounds he missed his way, and stepped suddenly over the perpendicular bank of a brook, or ha-ha, into the water below. The height of the bank above the water was 4 feet, the depth of the water about 2 feet 6 inches. He fell on to one knee, but was not immersed; so scrambled out and made his way back to the house in a state of some agitation. He was, in fact, at first hysterical. However, he got home, a distance of some miles, in a cab, and was seen by a doctor, who found no injury save a grazed knee. The next day the unfortunate gentleman went to his office as usual, but complained of shortness of breath and some pain in the loins. The hysteria had been controlled.

He began to suffer from what seemed to be flatulent dyspepsia; the wind was indeed incessant; he was obstinately constipated and passed little water. He became worse, yet attended intermittently to business. On November 30th, sixteen days after the accident, he died suddenly after drinking a glass of water to relieve his "wind."

A claim was made on a company in which he was insured on the ground that death had resulted from the accident. A *post-mortem* examination was ordered; no sign of any injury or surgical condition such as embolism was found. But there was recent dilatation of the stomach and some dilatation of the heart. Owing, however, to the undoubted fact that decomposition had advanced with extreme rapidity in a few hours, it was not, in the opinion of some who were present, possible to be definite as to the non-existence of fatty degeneration. Therefore the claim was disputed—apparently on the ground that the deceased died from heart failure, possibly in some measure due to a hypothetical precedent degeneration, but certainly in the last resort determined by the "flatulent dyspepsia," if not by the drink of cold water. It was also suggested that the flatulent dyspepsia was, together with the constipation, set up by lack of exercise, consequent on the slight knee injury and the rest at home. In fine, death was not due to the accident.

At this stage my opinion was asked by the solicitor for the widow, and I gave it to the effect that if there had been no accident the fatal event would not have occurred—that, indeed, the case was one of delayed shock. Learned counsel was then good enough to read me the case of Etherington, as illustrating the legal point that we might have to meet. This case is one of a gentleman who had a fall in the hunting field, went up to town the next day, fell ill and presently died of pneumonia. It was claimed that the pneumonia developed as a result of the vitality having been lowered by the shock of the fall, pneumococci being present in the body at the time. The claim was disputed on the ground that the terms of the policy denied benefits if there should be intervening causes between accident and death, and it was asserted that the pneumonia was such an intervening

cause. On appeal, the Lords Justices held that the insurance company was not entitled to relief if the intervening incident or cause were a link in the natural chain of events or causes developed between the accident and the death, inasmuch as the words of the policy were to be construed as applying only to the fortuitous intervention of some other or fresh agency causing death. They held that the pneumonia was no such fortuitous intervention, but an incident in the natural chain of events, and gave judgment against the company. In our case I certainly thought that there was not the intervention of any fresh agency; and so we went to arbitration. But after the hearing of witnesses as to fact, an offer of compromise was made and accepted, so that the question of delayed shock was never submitted to the learned arbitrator.

I think you will agree with me that it is important that the exact nature of cases such as these should be defined. In the case of Etherington there was a definite intervening illness, indicated at the *post-mortem* by the usual signs. Superficially it might seem that here the insurance company had a good case. But, apart from the luminous interpretation of the words of the particular policy by Lord Justice Williams, medically they had a bad one. Only the medical witnesses for the claimants might have put their case a little higher—"precised it," as the French say—and, instead of speaking generally of lowered vitality, drawn attention to the definite mechanism that exists in the autonomic nervous system for the production, in shock, of disturbance of function in special viscera. In my case, however, there was no gross or organic condition such as pneumonia to set up as an intervening agency; there was really no disease at all discoverable at the *post-mortem*, and until the time of death there had been no symptoms that required the assumption of what we call "organic change" to render them comprehensible. It was apparently because there was no more than functional disorder manifested that the insurance company hesitated to meet the claim. If there had been the fracture of even one bone, had there been a patch of pneumonia no bigger than a crown-piece that we could have sworn to, all would have been well. But neither the discovery of a fracture nor the existence of a pneumonia would have really made the case any stronger. And, after all, the man was dead. A healthy, sober man, who had never before spent a day in bed, died sixteen days after the accident while under treatment for flatulence and constipation. He died of "delayed shock," as it is called, truly and unquestionably, as did the persons whose cases I have already narrated, and as every day do people die who have broken a femur, or have been burnt, or suffer from post-operative ileus.

It is not necessary to labour the point that in this, as in other cases, the trauma was *unexpected*. But it links these fatal cases with the non-fatal ones, in which, equally, there is no symptom that may not be referred to functional derangement—namely, those of traumatic neurasthenia, wherein also it is clear that the protective mechanism of the body is taken "off-side." There is no time for preparatory adjustment of the blood distribution in the body to the purpose. And it is then easy to understand how, given a high shock value, under such circumstances the protective adaptation may be out of all proportion to the occasion, as when the telephone operator is excited by a rumour of fire. What the exact significance of the latent interval is, it is difficult to say, but it must be observed how generally there is some flatulence, which in slighter case may pass as due to dyspepsia, and in the more grave may lead to such distension that the surgeon's aid is invoked. Now this flatulence is not dyspeptic. It has, it is true, an intimate relation to the flatulence of what is called "neurotic dyspepsia," but, as I have tried to show elsewhere, (a) this flatulence, too, is an affair of actual gas secretion from the stomach and bowels, and brings the shock cases we have been discussing into line with those of acapnia, to which so much attention has been directed by Professor Henderson of Yale, and Dr. Crile. In all these curious cases in which gas secretion occurs three

(a) "Flatulence and Shock." H. K. Lewis, 1912.

systems are involved—the vasomotor, the autonomic nervous, and the adrenal. The direct connection between the adrenal system and the production of gas in shock and in acapnia has, I think, had light thrown on it recently by Falta and by Fuchs, who have shown that the adrenal system not only provides, as we know, a substance that influences the tone of the blood-vessels, heart, stomach, bowels, and other organs, but a substance or substances that seemingly control the internal respiration—the exchange of gases between the tissues and the blood. If, then, Cannon is right in holding the adrenal or chromaffine system responsible for the adjustment of the body in cases of shock, we can understand how it is that the symptom of flatulence, though present in varying degree, is a thread linking many of these conditions together.

Whether this gas secretion is indicative of exhaustion of the adrenal system, or whether it marks the excessive activity that heralds exhaustion, or whether it is sometimes or always an expression of perversion, rather than of excess or deficiency, it is hard to say. On the answer to these questions depends probably determination of the treatment that we should prescribe.

The practical notion that I put forward is that, just as we attempt to assay the life-value of any candidate for life insurance, so must we address ourselves to estimating the "shock value" or suggestibility of persons who are to be insured against accident.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Edward C. Hort, F.R.C.P.Ed. Subject: "The Causes and Treatment of Fever."

OPERATING THEATRES.

WEST LONDON HOSPITAL.

LAPAROTOMY FOR CHRONIC OBSTRUCTION OF PELVIC COLON.—MR. SWINFORD EDWARDS operated on a woman, æt. about 45, who some six years before had undergone a laparotomy, when, according to her account, her left ovary had been removed for some inflammatory trouble. For the last year or two she had been suffering with symptoms of colitis and considerable difficulty in getting a satisfactory evacuation of the bowels. She had passed at times much mucus, which was often blood-stained. Sigmoidoscopic examination revealed considerable ulceration in the upper rectum, and the instrument would not pass further than 15 centimetres. Thinking that the condition of ulceration was sufficient to account for her symptoms, daily injections of chinisol in the morning and protargol in the evening were prescribed. It was found that the patient could not retain very much in the lateral decubitus position, but on resorting to the knee-elbow position as much as two pints could be injected and retained. On seeing the patient again at the end of a month, it was found, by the use of the sigmoidoscope, that the ulcerative proctitis was all but well; but again it was found impossible to pass the instrument higher than 15 centimetres, and this difficulty was experienced on two or three subsequent occasions. As the patient wanted to return to the West Indies, and still complained of abdominal pain at times, accompanied by sickness and difficulty in getting the bowels open, Mr. Edwards advised a laparotomy, believing that the sigmoid colon was bound down by adhesions, probably due to the former operation.

On opening the abdomen, the diagnosis was confirmed, for the pelvic colon was found to be bound down to the left broad ligament and uterus; the adhesion between the bowel and uterus was exceptionally strong, being very dense and of the size of the index finger. On cutting through this, a residual abscess cavity was disclosed, containing in its centre a ligature of thick twisted silk. Mr. Edwards proceeded to excise the entire abscess cavity; this exposed the outer aspect of the mucous membrane of the bowel, therefore the wall of the gut had to be repaired by a double layer of sutures. Many other adhesions had to be divided in the left pelvic region. It was

then discovered that the patient still retained both ovaries. The abdomen was closed without drainage.

Mr. Edwards said that this was a very interesting case, especially in showing the use of the sigmoidoscope, for without its aid the condition of obstruction due to the adhesions could only have been guessed at. To account for the presence of the thick silk ligature found in the residual abscess cavity, he imagined that at the previous operation the colon may have been injured, and the ligature in question was the one used in closing the opening; though he thought it was somewhat extraordinary that such a thick ligature should have been employed for this purpose. The pain, he remarked, was no doubt largely due to the colitis and proctitis which at first were present, which pain materially decreased when the ulcerative condition of the bowel had disappeared under the treatment employed. In spite of this, however, abdominal discomfort and difficulty in evacuation still remained, owing, of course, to the adhesions.

It is interesting to state that the patient made a good recovery, and the action of the bowels was almost normal a month after operation.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

MEETING HELD THURSDAY, NOVEMBER 7TH, 1912.

The PRESIDENT, DR. AMAND ROUTH, in the Chair.

DR. G. R. DRUMMOND-MAXWELL brought forward a case of

ECLAMPSIA TREATED BY CÆSAREAN SECTION.

The patient was a primigravida, æt 19, admitted to Queen Charlotte's Hospital on July 23rd, 1912, at 9.35 a.m. Three fits had occurred before admission. She was having weak pains every twenty minutes, and the fetal heart sounds were regular and strong. The urine contained only a trace of albumen, there was marked œdema of the legs, and the blood pressure was 165mm. The cervix was rigid and only admitted the tip of the index finger. Two pints of saline were injected per rectum. By 6.30 p.m. thirteen fits in all had occurred, the labour had made no progress, and the patient had been comatose since 3 p.m. Cæsarean section was then decided upon and performed as soon as possible. Ether was the anæsthetic employed; the uterine incision was allowed to bleed freely; and two pints of normal saline containing 10 per cent. of glucose were poured into the peritoneal cavity after the uterus had been sewn up. No subsequent fits occurred, and both mother and child did well.

The author formulates the following indications for Cæsarean section in eclampsia:—

- (1) Fits occurring in a primigravida.
- (2) Onset of fits with no signs of the start of labour.
- (3) A rapid succession of fits where consciousness is not regained and coma is deepening.
- (4) Failure of advance of cervical dilatation after several hours of an expectant attitude with the prospect of many hours' delay before the second stage is reached.
- (5) Absence of any definite signs of improvement after eliminative treatment has been carried out for several hours.

The presence of all these indications constitutes a case of such gravity as to render the operation justifiable.

DR. J. M. WYATT drew attention to

LE FORT'S OPERATION FOR PROLAPSE,

and reported the results of eight cases.

This operation was described by Le Fort in 1877, the principle upon which it was based being that if the vaginal walls could be kept in constant contact with one another prolapse could not occur. He recommended the removal of a thin vertical strip of mucous membrane 2cm. wide from each vaginal wall;

he used silver wire sutures and laid stress upon the importance of bringing the whole width of the raw surfaces into apposition. Previous to Le Fort's operation various attempts had been made by Jobert de Lamballe, Gérardin, and others, to cure prolapse by constructing a vaginal partition. In 1889 André collected 40 cases treated by Le Fort's operation, 35 of which were successful.

In the author's opinion the operation is of great value in cases of proclivencia in old people where any form of pessary fails to keep the womb in position, and where laparotomy for fixation is contra-indicated. He then described the method of performing the operation as carried out at St. Thomas's Hospital by Dr. Tate, and recorded eight cases, in six of which the after history had been traced, and the result was successful.

SHORT COMMUNICATIONS.

Dr. RUSSELL ANDREWS introduced (1) a case of simultaneous uterine and extra-uterine pregnancy, in which "internal wandering" of the ovum seems to have occurred. (2) A small ovarian teratoma, containing, among other structures, brain and well-formed intestine.

Dr. C. HUBERT ROBERTS. Urgent Cæsarean Section in a case of contracted pelvis, with prolapse of the cord. Recovery of mother and child.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, NOVEMBER 1ST, 1912.

The President, J. O'CARROLL, M.D., F.R.C.P.I., in the Chair.

"VITALISM" IN PRACTICAL MEDICINE.

THE PRESIDENT delivered an Opening Address on this subject. Having given a brief review of the work of the Section during the thirty years of its existence, he addressed himself to the view of the nature of life put forward by Professor Schäfer in his recent address to the British Association for the Advancement of Science. He held that the physico-chemical explanation of life was unhelpful to the physician: that, however possible it might be that life might arise *de novo* from unorganised matter, it was nevertheless impossible to predicate that only the same forces, physical or chemical, operated in a living as in a dead thing. In life new force or forces came into existence, for which no convenient name other than "vital" force had been devised. That force showed its existence in many ways, but chiefly in its capacity of resistance to extinction. Vital resistance begot an adaptability to circumstances, a division of function among the parts of a compound organism for better maintenance and defence of the whole individual, and finally a power of compromise between contending or hostile organisms of similar or different kinds. That division of labour and power of compromise implied a certain social order which seemed an embryonic form of social ethics. The rise of an ethical or moral sense was a stumbling block in the evolutionary theory, running counter as it did to the doctrine of the survival of the fittest. For in a compound organism the cells of highest function were commonly the most vulnerable and the least capable of renewal; while the cells of lowest function usually made the longest defence, were most capable of proliferation, and were the last to die. The interdependence of high and low class cells gave each an interest in the survival of the others. In a community of similar organisms, within certain limits, the same law applied, and when it was forgotten the community suffered. Thus arose a communal morality, the ethics of mutual protection. If this view of life held good the rise of the ethical sense was a natural development and not a violent break in the history of life. Unless the terms "chemistry" and "physics" were to be extended quite beyond any accurate meaning they could not include ethics among their connotations. If they did they would have as little value as

Professor Schäfer ascribes to "vitalism." In the practice of medicine the "vital" conception of disease was all important. It taught one to separate symptoms, which were essentially morbid from those which indicated resistive or protective processes, and thus led to the adoption of treatment which would help and not obstruct the vital processes which made for survival of the individual.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD ON NOVEMBER 6TH, 1912.

President, Mr. J. M. COTTERILL, in the Chair.

Mr. J. W. STRUTHERS read a paper on
PERFORATED DUODENAL ULCER,

which will be found on page 542.

In the discussion that followed Mr. COTTERILL remarked that the absence of a history of melæna in so many cases was rather remarkable. In cases of doubt he preferred to make an incision low down in the pelvis, examine the appendix, and, if necessary, make a second incision higher up. In some of the difficult cases the incision might otherwise be rather long. The lower incision was useful for drainage. We were not yet in a position to say that gastro-enterostomy should be done in every case which could stand it. Some cases gave excellent results without gastro-enterostomy, and results were not always perfect after that procedure had been followed.

Professor CAIRD congratulated Mr. Struthers on his good results. He thought the practitioner was becoming more alert to the urgent necessity of early operation in these cases. He had frequently noticed improvement of the pulse after the abdomen had been opened, but he was not so certain that the good effect was always maintained after washing out the peritoneal cavity. He always at least washed out the pelvis. He favoured gastro-enterostomy after closure of the ulcer. There might be considerable narrowing of the duodenum.

Mr. CATHCART said that if the amount of effusion was slight there was no necessity to wash out but it did no harm. It often did good in removing fluid from the region of the diaphragm. He had seen sub-phrenic abscess follow in cases where washing had been omitted. He thought the presence of symptoms depended on the presence or absence of inflammation round the ulcer. The pain was sometimes due to spasm following hyperchlorhydria.

Professor ALEXIS THOMSON was convinced of the great advantage of gastro-enterostomy, and if he were to be operated upon himself for ruptured duodenal ulcer he would certainly suggest that gastro-enterostomy be considered by the operator. In addition to the other reasons which had been adduced in favour of this course the ulcers were frequently multiple. His experience was that of the author with regard to bleeding. The cases with much bleeding did not often perforate.

Mr. WALLACE wished to emphasise the importance of not overlooking the condition during the latent period. He had operated on three cases in which symptoms had entirely disappeared by the time he had seen them. He had also had difficulty in cases where the pain was referred to the right iliac fossa. He favoured gastro-enterostomy, but reminded the meeting that an American surgeon had analysed a long series of cases and found the results after gastro-enterostomy, and those in which it had not been performed were about equal.

Mr. MILES said that when he was in doubt as to the seat of trouble he made a pelvic incision, and passed a tube into the pouch of Douglas. From the characters of the fluid he could tell the seat of rupture, and he then made a second incision where it was needed. It was probable that the pylorus contracted when the rupture took place. He had once seen a perforation take place while the patient was undergoing operation. The use of cat-gut or silk was a

matter of individual preference. He preferred the latter, as a smaller needle could be employed. He always washed out the peritoneum, though he was not prepared to say that was a necessary proceeding. He did not think the position that gastro-enterostomy should always be performed had yet been reached, and if that were laid down it might discourage country practitioners from undertaking the operation in emergency. In four cases he had performed pyloroplasty by splitting the pylorus longitudinally and stitching transversely. The pyloroplasty was, however, not equal to the gastro-enterostomy opening.

Mr. DOWDEN said it had been his fortune to open the abdomen on three occasions for typical symptoms of ruptured duodenal ulcer, but nothing had been found. In distinguishing between ruptured duodenal ulcer and acute appendicitis he had found percussion very useful as a means of eliciting the seat of most tenderness. He preferred to make two separate incisions in cases of doubt. In closing the ulcer he cut through the pylorus and continued the cut down the long axis of the duodenum, thus producing a pyloroplasty. He always had the pouch of Douglas flushed out while he was stitching up and then closed up everything, leaving as much fluid as possible in the peritoneal cavity.

Mr. WILKIE referred to the age incidence of the condition. There were two groups. One affecting young men and the other in patients aged from forty-eight to sixty. In the latter there was generally a history of hard work and alcohol, and there was nearly always arterio-sclerosis. The ulcer in this group was almost always at the upper border of the anterior wall, where there was great difficulty in getting an anastomotic blood supply if one artery were interfered with. He had seen duodenal ulcers in twelve post-mortems, and in only two cases had the condition been suspected during life.

Drs. WILLIAM GUY and J. S. ROSS read a paper on NITROUS OXIDE AND OXYGEN AS AN ANÆSTHETIC FOR DENTAL AND SURGICAL PURPOSES.

It was contended that this method had three great advantages. (1) It gave an anæsthesia closely resembling sleep. It interfered little with respiration, circulation, and alimentation. It was safe. Why it had not found a wider field was the cumbrous nature of the apparatus hitherto in use. A simple form of apparatus was described, by means of which it was possible to administer measured doses of both gases. The method lent itself admirably to short operations, but it was probable that the expert would be required to carry out the administration in prolonged surgical operations.

Mr. WALLACE said he had seen the method in use in surgical operations. It required the assistance of an expert administrator, but its field of usefulness was just in those cases where an expert anæsthetist was likely to be called upon.

Mr. WADE said that the method was certainly of value in those cases where a fatty liver and other conditions might make the surgeon fear the effects of a general anæsthetic.

Mr. J. S. FRASSE, while not denying that this might be an excellent method, said that ethyl chloride had been given in the ear and throat department of the Royal Infirmary in some 9,600 cases without any inconvenience to the patients, and the simplicity of the method was a great advantage.

Dr. DAWSON TURNER read notes on the TREATMENT OF A CASE OF LYMPHO-SARCOMA BY RADIUM.

The patient was a male, *æt.* 65. A tumour had been removed from the axilla, and had recurred in the region of the clavicle with enlarged glands. Twenty milligrammes of radium bromide in an aluminium case had been inserted into the mass, and 40 milligrammes had been applied through a silver screen to the tumour externally. Improvement was soon apparent, and the tumour became removable. This was done, and a capsule of radium had been placed in the cavity. The patient had been well for over a year.

Professor ALEXIS THOMSON remarked that the case was both clinically and microscopically one of small-celled sarcoma, and the result had been very gratifying.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, OCTOBER 31ST, 1912.

The President, Dr. H. J. MACEVY, in the Chair.

DISCUSSION ON

THE PREPARATION, CHOICE OF ANÆSTHETIC AND ITS MANAGEMENT IN DIFFICULT TYPES OF PATIENTS DURING ABDOMINAL AND PELVIC OPERATIONS.

Dr. DUDLEY BUXTON, in opening the discussion, said that the underlying physical and pathological states which produced types of patients were the essential matters for the anæsthetist to study. Adopting as his guide that the patient's safety, the suitability of the anæsthetic to the particular operation, and the predilection of the operator for any anæsthetic or method should be placed in this order of importance, the anæsthetist had yet to remember that the success of the operation might depend upon whether the surgeon's *desiderata* were granted him, and upon this success ultimately must depend the patient's safety or chance of speedy recovery.

The environing conditions of the patient were those (1) outside the region of operation, the age and sex, his physique, his habits as regards drugs and alcohol, and so on, and such blood states as anæmia or toxæmia—*e.g.*, sepsis, glycosuria, albuminuria, cholæmia, and the presence of inter-current organic disease affecting the respiratory, the circulatory, or the hæmopoietic systems; (2) those due to abdominal or pelvic affections. Thus abdominal distension, sepsis and fever, with in some cases vomiting, possibly stercoraceous, introduced fresh factors into the problem presented to the anæsthetist. Such conditions had to be met partly by preparation, which included hygienic and drug treatment for some period before the operation, (3) the choice of the anæsthetic and method suitable to the case which offered the least likelihood of peril at the time of the administration of the anæsthetic, and promised the fewest deleterious after-effects.

Dr. Dudley Buxton pointed out the value to all concerned of giving the skilled anæsthetist the opportunity of studying his case with the home doctor before the operation. Subsequently the nature of the operation became a serious consideration, if, for example, it involved severe hæmorrhage, massive shock or prolonged and severe trauma. In ordinary circumstances dieting was essential, and adherence to the normal hours and habits of the patient should be practised, as otherwise dyspepsia and malassimilation occurred. Severe purging and even enemata were dangerous when employed on the day of the operation. Copious hot water ingestion or saline clysters given for a week previous to abdominal sections offered many advantages, as did rectal feeding with easily absorbed foods such as glucose.

The anæsthetic must be chosen after study of each individual case, and what was even a more important matter, the method of using it. Where lung complications existed chloroform with oxygen was usually the best anæsthetic. In other cases ether usually in sequence commonly proved suitable, but should be preceded by a dose of atropine. The question of shock, whether due to trauma, rough handling of viscera, or to hæmorrhage necessitated the adoption of a method permitting variation in the degree of narcosis appropriate to the condition of the patient and the exigencies of the operation. In all depressed states whether due to pre-existing blood disease or trauma, the chances of the patient's survival or ultimate recuperation were largely a question of the amount of toxæmia itself, in part pre-existent and in part super-added by the introduction of large amounts of an anæsthetic or analgesic. Hence the importance of giving as little as was consistent with the requirements of each case. Preliminary injection of morphine, atropine and other hypnotic narcotics was valuable, both because the nervous system was soothed, psychic shock diminished, and the amount of the general anæsthetic required was materially decreased. Special reference was made to operations involving severe shock—*e.g.*, prostatectomy, panhysterectomy, and

intestinal stoppage was made, and in the last case Dr. Dudley Buxton advocated lavage and constant stomach drainage under intravenous ether infusion, and intravenous ether infusion was invaluable in cases in which considerable loss of blood occurred. The difficulty experienced in operations upon the upper abdomen due to rigidity of the recti was, the speaker believed, commonly due to partial asphyxia, the recti being muscles concerned in respiration, the causes and remedies of which he described. Many cases were suitable for a combined method, preliminary alkaloid injection with spinal anæsthetic or local analgesia, followed by general anæsthesia. The dangers which were very real of psychic shock had to be reckoned with whenever spinal and regional analgesia were employed alone, and these were accentuated in the case of the highly nervous and the neurasthenic.

Dr. G. A. H. BARTON said the procedure which he found most generally useful in abdominal operations was (1) a preliminary alkaloidal injection; (2) a rapid induction by means of a little C.E. mixture and ethyl chloride on a Skinner's mask; (3) maintenance thereafter of anæsthesia by means of open ether given in a special apparatus, which he showed. Shock might be present before or develop during operation; since adopting the method above described he rarely experienced the latter event; morphia or ether did much to abolish it; warmth, position, saline infusion, and oxygen through alcohol were beneficial; pituitrin and adrenalin were useful, but must be used with caution as their exhibition was not devoid of danger in some circumstances. Strychnine he still considered valuable, but rather as a preventive. In the plethoric, muscular, and alcoholic, ethyl chloride was best avoided in the induction owing to its liability to cause abdominal rigidity in these types; where it occurred chloroform might have to be given, but he generally found oxygen and a light anæsthesia more useful. He spoke of the respiratory difficulties that frequently arose in the edentulous, and said that his practice when the patient had a complete set of upper and lower teeth on vulcanite plates was to leave them *in situ* during the operation. Where lung complications were severe inhalation anæsthesia should be abandoned and resort had to intraspinal analgesia or intravenous ether. On the whole he deprecated the administration of chloroform in abdominal operations, and particularly when sepsis was present. Septic toxæmia was a cause of degeneration of liver cells and acidosis and chloroform made the condition worse. Sepsis *plus* chloroform was, in his opinion, the cause of many of the deaths occurring from fatty acid poisoning a few days after operation in acute appendicitis and allied conditions.

Mr. RAYMOND JOHNSON referred especially to the difficulties met with in certain acute abdominal conditions in which the urgent need of immediate operation rendered any special preparation of the patient impossible. In the presence of toxæmia he entirely agreed with those who held that chloroform should be avoided and regarded the choice as lying between ether administered by the open method and spinal anæsthesia. With increasing experience he had become more and more impressed by the value of the latter, especially in such cases as acute appendicitis, particularly in young children, in whom the toxæmia was often profound and the mortality still high. Spinal anæsthesia was also particularly useful when the nature of the operation necessitated very complete relaxation of the abdominal muscles. He had found the method very valuable in operating for acute intussusception in young children. The closure of the abdominal incision in these cases was often very difficult if the muscular relaxation was incomplete, on account of the tendency of the omentum and intestine to protrude. Mr. Johnson was specially interested in Dr. Buxton's remarks on the dangers resulting from great abdominal distension and vomiting in some cases of obstruction, and was of opinion that in some cases the safest course was to employ local or regional analgesia, and, in the first instance, merely drain a distended coil of gut. In prolonged abdominal operations, such as the combined abdominal and perineal method of removing the rectum, he thought

the choice should lie between the inhalation and intravenous methods of administering ether, and that the decision should turn upon the general condition of the patient.

Finally, he referred to the occasional difficulty met with in closing vertical incisions in the upper region of the abdomen, and caused by the wide retraction of the divided edges of the posterior layer of the rectus sheath. He was sure that this difficulty was often not due to imperfect muscular relaxation, and suggested that the elasticity of the chest wall was an important element in causing the retraction of the divided aponeurotic layers.

Mr. J. D. MORTIMER remarked that, as pointed out some years ago by MacEwen, a general anæsthesia even when pushed to a full extent did not abolish marked reflex disturbances during some surgical proceedings, particularly in neurotic, alcoholic and rickety subjects: such might occur in the total absence of preceding asphyxia. He had found a combination of light general anæsthesia with spinal analgesia valuable in such operations as prostatectomy and radical cure of hernia—complete relaxation being obtained and shock avoided, without the dangers of a deep narcosis on the one hand or of "psychic shock" on the other; which last if spinal analgesia were employed might be serious.

Dr. J. LEON JONA, of Melbourne, said he was pleased to hear Dr. Buxton advocate the warming of the operating table. This was a point on which surgeons could take a lesson from those who experimented on animals. The maintenance of the body temperature at its normal level during the course of the operation and afterwards would, he felt sure, reduce the amount of so-called "post-operative shock."

Another point mentioned by Dr. Buxton was the preliminary administration of morphia or some such drug, which certainly in dogs gave good results and necessitated the use of very much less ether or chloroform. There were a few other points, too, attention to which on the part of the surgeon would undoubtedly be of benefit to the patient, and so assist the anaesthetist in his work, and these were gentleness in manipulation of abdominal contents, a little more respect for and better treatment of the parietal peritoneum, which in many abdominal operations was very much rubbed about by swabs, packs, etc., and celerity of action.

Dr. COPELAND, of Toronto, Canada, speaking, said: Mr. President, I thank you for the invitation extended to visitors to take part in this discussion. It has given me a great deal of pleasure in listening to Dr. Dudley Buxton's able address. I may say that I am somewhat conversant with the way anæsthetics are given in both Canada and the United States, and that, in general, the methods used there are very similar to those described by the speaker. I am surprised that no mention has been made of nitrous oxide and oxygen anæsthesia, supplemented by morphine and atropine, and perhaps scopolamine. For long anæsthesia, especially in abdominal operations, it seems to be very little used in England. I have seen it given for over four hours in a very difficult abdominal case in the Montreal General Hospital with excellent results. In septic cases, such as an acute fulminating appendicitis, it is the inhalation anæsthetic *par excellence*, not causing the slightest degeneration in any of the solid organs, such as the liver and kidneys, or of the blood. If further relaxation be needed than it gives, an exceedingly small amount of ether added will secure it. Nitrous oxide and oxygen seems to me to be ideal in most cases as an introduction to ether.

Since coming to England, I have been surprised in seeing, in many hospitals, a most dangerous habit practised by men who ought to know better—namely, that of continually touching the cornea with their fingers to test the eye reflex. In Canada and the United States, it has practically been given up, and in some States of the Union it has been declared by the Courts to be malpractice, as corneal ulcers have resulted and sometimes blindness. It is the more inexcusable because unnecessary. The same information can be gained by touching the eyelashes. I should like to ask Dr. Dudley Buxton's opinion on this subject.

Crile has shown that one of the great factors entering into shock is the loss of carbon dioxide from the blood, caused by over-ventilation of the lungs by excessive breathing caused by pain and other reflex stimuli, which the speaker has mentioned. In the administration of nitrous oxide and oxygen a great deal of shock can readily be overcome, as Crile has shown, by restoring carbon dioxide to the blood, either by re-breathing, or better, by giving a definite amount of carbon dioxide. The patient also comes out of this anaesthetic with extreme rapidity, with a mind comparatively clear as I have lately had the experience of trying personally.

Dr. BLUMFELD and Mr. HOPE also spoke.

In replying Dr. DUDLEY BUXTON reminded his hearers that he had been obliged to limit his remarks, for the time allotted was too short for so large a subject. The great value of Dr. Hornibrook's work lay in his proof that chloride of ethyl should be given by an open rather than by a re-breathing method. The corneal reflex was one which he believed should be seldom invoked; it was unnecessary, and the eye was often damaged by the finger. The use of nitrous oxide and oxygen in major surgery was, he believed, best restricted to its action in sequences such as before ether. In spite of Dr. Crile's and Dr. Peter's splendid work he was not convinced that the level of narcosis this mixture provided was convenient in the types of cases under consideration. Rapid resumption of consciousness was not commonly an advantage; he certainly believed that chloroform was undesirable in most cases of acute septic disease.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, NOVEMBER 7TH, 1912.

President, Mr. ROBERT JONES, F.R.C.S., in the Chair.

Dr. C. RUNDLE read a short paper on
CONSIDERATION OF TEMPERATURE IN SELECTION OF
CASES FOR TREATMENT BY TUBERCULIN.

Charts were shown by lantern screen demonstrating the reaction and control of temperature obtained by the administration of tuberculin. In those cases where temperature had been normal for a week or more the administration was begun with a dose of .00005 increased rapidly. The result was satisfactory. In another class of case with an evening rise of temperature to 99° F. or 101° F., many authorities discouraged the use of tuberculin, but Dr. Rundle thought that these were cases where the most brilliant empirical results were obtained.

In the cases where there was a superadded infection such as a streptococcal an autogenous vaccine was useful. Dr. Rundle had in one case been able to isolate such an organism from the blood and administer a vaccine. Tuberculin is of use when the secondary infection has been overcome, as shown by the temperature ceasing to oscillate. In cases where the temperature was from 101° F.—102° F., with perhaps a remission of a degree or so, but never coming to normal, the results of tuberculin were unfavourable.

Dr. Rundle remarked that he had used a preparation of formalin called hæmasepsin and found that it controlled the temperature after a marked reaction; on stopping the administration the temperature again rose, but could again be controlled. In this case it was found that the same quantity of normal saline produced a similar reaction and controlled the temperature, but after prolonged treatment and the use of eighty injections the case terminated fatally.

Dr. NATHAN RAW read a paper on

THE TREATMENT OF TUBERCULOSIS WITH TUBERCULIN.

The paper was based on 640 cases which had been treated. Dr. Raw's impression was that in a great many cases permanent good was done, that where there was acute disease complicated by superadded infection, little could be expected. In all cases other means of treatment were also to be used if possible, such as prolonged open-air treatment, food, cod liver oil, and general hygiene. It was difficult to decide which cases would improve under the treatment, but

the earlier a case was put under treatment the better. In the choice of the form of the remedy Dr. Raw used Koch's new tuberculin human and bovine, and he preferred a mild dosage. A temperature of 101° F or more was a contradiction to the use of tuberculin. So also was hæmoptysis on account of the local hyperæmia that was produced. In cases of virulent infection tuberculin was of little use. Some of the best results were obtained in gland infections, many of these cases were caused by the use of tuberculous milk, and were therefore of the bovine variety, and in these cases Dr. Raw considered there were better results from the use of human tuberculin. It was most important not to give tuberculin in any case where there was pent up pus or caseating material, all such deposits should be evacuated first, or otherwise the treatment would cause local reaction and a general diffusion of the disease. As little as possible should be done with the knife beyond incision of the part to liberate the pus.

Dr. Raw began treatment with a minimum dose of 1-10,000 mgm. If there was no reaction the next dose was given in a week, and slowly increased to 1-100 mgm. The patients usually had a feeling of well-being and the temperature became normal. Dr. Raw thought that with careful dosage undue reaction was due to errors in the *technique* of administration. In making a diagnosis he used Mors's ointment for children and Von Pirquet's test. Those were useful, but in an acute illness the positive reaction would not prove that the acute illness was due to tuberculosis; an old quiescent deposit would give the same reaction. It was not to be expected that in any apparently cured patient a permanent immunity had been secured.

In the discussion that followed Dr. T. R. BRADSHAW congratulated Dr. Raw on the moderation with which he had stated his case for tuberculin treatment. Dr. Bradshaw had watched Sir A. Wright's early work with great interest and seen in his hands very striking results, but his further experience had not been so favourable; in many cases there was only improvement at first. Dr. Bradshaw doubted the value of Von Pirquet's test, as a reaction could be obtained in about 60 per cent. of normal subjects. If the reaction is a form of anaphylaxis it may be obtained during the whole of a susceptible individual's life, and would therefore be no guarantee of the presence of tubercular infection.

Sir JAMES BARR had found that many cases did very well with tuberculin treatment, but there was one class where no improvement took place—in the young subject with bad indigestion and rapid pulse.

Dr. CRACE-CALVERT did not think it was necessary to use bovine tuberculin in the human variety of infection; he used bacillary emulsion, and had not seen severe reaction. He used smaller dosage than Dr. Raw—one hundred-thousandth mg., and increased gradually. He was sure that tuberculin was not going to revolutionise the treatment of tubercle, and he deprecated the publication of some statements intended for popular consumption, and quoted one in which it was stated that with tuberculin victory over the disease was never in doubt.

Dr. BUCHANAN pointed out that the reaction test was of small value from a diagnostic point of view, and its value was a diminishing one as life advanced from the age of three years. He had found that the more definite the reaction the more resistance there was to the tubercle bacillus. Dr. Buchanan thought we should be much helped if some definite standardisation of tuberculin could be arrived at so as to allow a real comparison of results obtained by various workers. He thought that in mixed infections tuberculin did little good. If a vaccine—even a stock vaccine—were used alternatively or together with tuberculin it would be an important advance. Dr. Buchanan thought we might safely push the dosage much farther than was usually done. In normal subjects 5 per cent. of leucocytes exhibited lobing, but in those with low immunity 80 per cent. of leucocytes were lobed. This observation could be made use of to indicate dosage, which should be pushed until the lobing came back to normal.

Professor ERNEST GLYNN did not think glandular

tuberculosis was so often due to bovine infection as Dr. Raw supposed, and could not believe there was any advantage in treating bovine tuberculosis by human tuberculin and *vice versa*. The ideal would be to treat a subject by tuberculin from his own bacillus.

Dr. MOSS, Dr. FAIRFIELD THOMAS, and Dr. STOKES also spoke.

In reply, Dr. RUNDLE said that he was aware that the Public Health Service of the United States had reported unfavourably on the use of tuberculin and that in France its use was much decried.

Dr. RAW, in reply, quoted the opinion of Von Pirquet himself that a positive reaction might be obtained, but was the result of a very early infection in childhood the forces being obsolescent. This was borne out by our common experience in the p.-m. room. The reaction was valuable in the negative sense, but even there an acute infection may overpower it. Dr. Raw quoted experiments in cattle which proved that they could be immunised by bovine, but not by human tuberculin.

SPECIAL REPORTS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. ANNUAL MEETING AND THE INSURANCE ACT.

At a meeting of the Council of the Royal College of Surgeons of England on Thursday, November 14th, the President, Mr. Rickman J. Godlee, reported that the following resolutions will be moved at the Annual Meeting of Fellows and Members on Thursday, the 21st inst. :—

To be moved by Mr. H. Nelson Hardy :

That this Meeting of Fellows and Members approves and endorses the action of the Council taken during the past year in reference to the National Insurance Act, and agreeing with the Council's statement in its letter to the Insurance Commissioners, dated February 1st, that the administration of medical benefits cannot be carried out under the Act, as it at present stands, with due regard to the interests of the public and the welfare of the medical profession, trusts that in the coming year nothing will deter the Council from discharging its duty to its Fellows and Members as firmly and as faithfully as it has done in the year that is past.

To be moved by Sir Victor Horsley, F.R.S. :

That this twenty-eighth Annual Meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council which, as now constituted, only represents those Members who also hold the Fellowship; and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation.

To be moved by Dr. W. G. Dickinson :

That this Meeting regrets that the Council has not called a special meeting of Fellows and Members to consider the National Insurance Act.

The President further reported the steps which he had taken in regard to a letter from the National Health Insurance Commissioners with reference to the position of Resident Medical Officers under the Insurance Act, and submitted the following copy of a letter which he had addressed to the Commissioners on the subject :—

Royal College of Surgeons,
Lincoln's Inn Fields, W.C.

October 17th, 1912

Sir,—The Council of the Royal College of Surgeons has not had the matter referred to in your letter of the 3rd instant under formal consideration, and do not propose to avail themselves of the opportunity afforded them of sending Representatives to give evidence before your Committee.

In acknowledging your letter I may, however, point out :

(a) That Resident Medical Officers in Hospitals naturally fall into two classes—first, those who receive small salaries or merely board and lodging, not because their services are not worth more, but because they discharge their duties for small payment in considera-

tion of the advantage they gain from the instruction they receive in doing so; and, second, those who hold more or less permanent appointments and whose salaries exceed the Income Tax limit. Neither of these classes, therefore, appear to be employed persons under the meaning of the Act.

(b) That, in the case of sickness, it is the invariable custom for such officers to be offered treatment in the Hospital to which they are attached, an offer which is, in most cases, taken advantage of. It does not appear to be equitable to exact payment from both parties for that which is voluntarily given by one and for which the other has to pay nothing.

(c) It is practically certain that none of those who receive low salaries, and could, therefore, conceivably be held to be insurable under the Act, would continue such insurance after the completion of their short term of office. The result of including them would, therefore, be that the Hospitals would have to pay a perpetual tax in proportion to the number of these officers, who, in their turn, would have to pay for a few months for what under no circumstances could benefit them.

It must not be forgotten that Resident Medical Officers are most unlikely to join Approved Societies, and at the best, therefore, would only be Deposit Contributors.—I am, Sir, your obedient Servant,

(Signed) RICKMAN J. GODLEE,
President.

The Secretary,

National Health Insurance Commission

(England), Buckingham Gate, London, S.W.

THE LOCAL GOVERNMENT BOARD REPORT. (a)

This Report includes the whole year 1911, and the first three months of 1912. On the whole the number of persons in receipt of Poor Law Relief shows a notable and satisfactory decrease, especially during the year 1911. This is largely attributable to the fact that since January 1st of that year, persons were no longer disqualified from becoming old age pensioners by reason of having received Poor Law relief at some time since January 1st, 1908.

March, 1912, shows a large increase of paupers—more than sixty-three thousand in England and Wales—over the corresponding month of the previous year. This was directly due to distress occasioned by the dispute in the coal trade, which occurred in that month. This rise lasted till the second week in April, when the number fell rapidly, but even at the end of May there was an excess, as compared with 1911, of nearly fourteen thousand, which must be largely traceable to the effects of the dispute.

A striking fact about this increase is that only a comparatively small number of unions was seriously affected. Sixty-five per cent. of the increase was confined to thirty-two unions in England and Wales, and the metropolis was practically unaffected. This crisis was satisfactorily dealt with by means of an order containing provisions specially designed to cope with exceptional distress.

The problem of the administration of relief to the houseless poor of London has been difficult of solution, partly owing to the fact that there was no single metropolitan authority to deal with the matter. At the end of 1911 an Order was made transforming the whole of this department to the managers of the metropolitan asylum district. It is hoped that this departure will facilitate the distribution of the houseless poor among the several casual wards and by keeping them in close touch with the various charitable organisations will give them a chance of regaining an independent position.

Old-age pensions show a large increase, due to modifications in the statutory condition under which various classes of the population were rendered eligible. The total increase for the United Kingdom is 3.8 per cent.

In addition to the Board's Report copies of all orders and circulars issued, and of reports of the Board's general inspectors with regard to poor law administration are included.

(a) "Forty-first Annual Report of the Local Government Board, 1911-1912." Part I.—Administration of the Poor-law, the Unemployed Workmen Act, and the Old Age Pensions Act. London: H.M. Stationery Office. 1912. Price 1s. 4d.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Nov. 16th, 1912.

At the Obstetrical and Gynæcological Section of the meeting of the Naturforscher und Aerzte, Hr. Edmund Falk, Berlin, reported on experiments he had made on the

ROENTGEN TREATMENT OF TUBERCULOUS PERITONITIS.

Making use of guinea-pigs for his experiments, he injected tubercle bacilli into the peritoneal cavity, setting up a local tuberculous peritonitis. The treatment consisted in opening the abdomen and then, whilst the abdomen was still open, applying the Röntgen rays. The tubes made use of were soft ones, the object being to set up a high degree of hyperæmia. As a matter of fact a greatly increased collection of lymphocytes within the peritoneal cavity was observable as long as a week after the application of the rays. For control purposes a series of the animals was simply operated on, the abdomen being opened, but without subsequent application of the X-rays, a second series was left without operation,—i.e., in fact, without local treatment of any kind. The irradiation up to a full erythema dose was borne without any trouble, or injury. The result of the experiments on 22 animals was the following: In animals in whom the treatment was carried out at a stage when the liver, spleen or kidneys were also affected no recovery took place, but even then the infection was less than in the animals that had not been rayed at all. When the operation was carried out at a stage when the tuberculosis was limited to the peritoneum and the great omentum permanent recovery took place after X-raying in animals where no such recovery took place in animals that had had the abdomen opened, without the addition of the Röntgen treatment.

Hr. Frank, Cöln, gave an address on

SUBCUTANEOUS SYMPHYSIOTOMY.

He said that when properly indicated, he held symphysiotomy to be the most "blessed" operation in the whole domain of obstetrics. Asepsis in the wound, avoidance of free hemorrhages were the chief things. Subcutaneous symphysiotomy came the nearest to the ideal. Free bleeding was avoided by drawing the clitoris and urethra with their vessels aside with the left hand. Asepsis was provided for by the use of a simple knife with which the symphysis was divided. First the lower half was cut through along with the crucial ligament, then the upper half from front to back. The incision was at once closed by a deep catgut suture. The speaker considered the following to be the important points: (1) That when the thrust was made the hip bones should be drawn apart, and that at the last moment of dividing they should be pressed together again. (2) That for some time after, by light pressure on the symphysis, a large hæmatoma would be obviated. (3) An exact aseptic dressing should be applied, strong enough to hold the pelvis firmly. (4) If there was a suspicion that the bladder was injured a permanent catheter should be left in it. The procedure should be made use of in primipara cases as little as possible.

He had performed the operation in 91 cases, most of which were in a febrile state. Of the multiparæ, of which there were 69, every mother and every child was saved. Of the primiparæ, 22 in number, one mother was lost and 7 children.

Hr. Leinweber read a paper on

FORCEPS DELIVERY.

He said the forceps might be the most useful instrument in midwifery, or they might be the most dangerous. They were dangerous inasmuch as they were applied too early, before the soft parts were sufficiently dilated. He warned his hearers, therefore, not to give way to the anxious and urgent solicitations of bystanders to end the labour, so long as the soft parts

were not sufficiently dilated. Before this stage, before complete dilatation of the os uteri, it was a direct danger to put on the forceps. In the case of brow presentations, however, the attendant should not wait too long, otherwise that part would come too far forwards. No correction of the position should be undertaken with the forceps, as the back could not be rotated by them. The natural mechanism must be imitated with the forceps. We should not, as desired by Olshausen, sink the forceps so far that the forehead appeared under the symphysis, the blade should rather be raised as soon as the hair border appears underneath the symphysis so that this served as a "hypermochlion." If this was done operative delivery in brow presentations and in normal flattened pelvis was not difficult. In spite of this, however, the application of the forceps in brow cases required the greatest caution, especially in the bringing forward of the handles so as to avoid slipping and also too great a pressure on the perineum.

AUSTRIA.

Vienna, Nov. 16th, 1912.

STENOSIS OF THE PHARYNX.

At the Gesellschaft, Marschik showed a patient on whom he had operated for a stenotic condition of the fauces that had gone on shrinking for some time from a scleroma. A year ago he was treated in Chiari's clinic for a diffuse scleroma of the nose, pharynx and gums, and had been constantly under treatment since the end of 1910 by Chiari, who excoculated the nose and applied the Röntgen rays to the exposed infiltrations in pharynx and mouth, which acted beneficially on the external parts, but failed to improve the mouth and pharynx. Owing to this failure, the isthmus faucium grew narrower, notwithstanding the daily dilatation. At the beginning of the present year his condition was so bad that tracheotomy had to be performed to relieve the breathing, and gradually the swallowing got so bad that cachexia and inanition made it painfully evident that something else must be done to relieve the stricture of the pharynx. Accordingly a plastic operation was resolved on, and the whole of the fauces and soft tissue of the mouth dissected out, with a number of the back teeth. After thoroughly clearing away all the morbid growth, the next step was to find a flap to cover the denuded surface. This was selected from the left side of the neck commencing below the beard and ending with the base over the sterno-cleido mastoid. An opening was then made through the pharynx, as in the radical operation for the removal of the tonsils, and the flap carried into the mouth and fauces and fixed to the prevertebral surface; with a circular opening in the flap the rest of the mouth was covered. All healed up with the exception of the opening through which feeding was conducted and allowed to granulate, as tampons were kept in the mouth to hold the covering in place. Finally the edges of the wound were freshened and a few stitches inserted to close the wound. Schrotter's catheter has been used since the operation, although the patient has been able to swallow perfectly and has put on 12 kilograms of weight since the operation.

PROTOZOA IN PEMPHIGUS CHRONICUS.

Lipschütz next related his late efforts to discover the real aetiology of pemphigus, as sometimes it has been attributed to nerve disease, at other times to bacteria, etc., leaving us in difficulty to say what it is really due to beyond a change in the cutaneous surface, leaving the internal intact, although some endogenic change must have taken place in some of the organs and the noxa carried by the bloodvessels to the skin. A similar dermatotropism is met with in animal diseases, such as chicken-pox, the pocks of the sheep, and the foot-and-mouth disease. He examined the fluid from the vesicles of eleven patients cytologically on moist "Giemsa" colouring matter, and found ovoid bodies, some of them rather elongated with dark red nuclei, which appeared in some of the cells as if they were tied in bundles, in others two or three together. These were easily distinguished from the eosinophile granules.

From their general appearance Lipschütz has named the phenomenon "anaplasma liberum" for want of a better explanation, as they are easily distinguished by this from the cloudy appearance of the epithelium and leucocytes. This anaplasma liberum is not constantly found in pemphigus, as it could not be found in pemphigus vegetans, but is regularly present in pemphigus vulgaris and dermatitis herpetiformis.

Sternberg said that he had met with the same bodies in the spleen of a patient who had died with pemphigus. He also found similar bodies in the lymphatic glands, several of them having the form of protozoa, but he would not like to dogmatise on the subject without further investigation.

Wiedenfeld remarked that the different groups of pemphigus—vulgaris, circinnatus, foliaceus, acutus, and vegetans, were aetiologically different, and, indeed, could be separated clinically from one another, although the general appearance is similar. Pemphigus vulgaris and pemphigus foliaceus are easily transmissible and changeable. The other forms can be transmitted to the healthy skin by severe pressure and then applying the fluid of a vesicle to the injured surface, covering it with an impermeable stuff, which will sometimes produce a vesicle, though not always. Intracutaneous injections of the fluid, however, will produce a bulla. The aetiology of the first group is therefore toxic, the second bacterial.

HUNGARY.

Budapest, Nov. 16th, 1912.

At the recent meeting of the Budapest Royal Medical Society, Dr. A. Vas read a paper on

DUODENAL ULCERS

In addition to the signs and symptoms generally emphasised, he called attention to the fact that in his ten operative cases gastric hypersecretion was a constant finding, and in a degree seldom encountered under other conditions, not even with gastric ulcer. Hypersecretion therefore suggests either gastric or duodenal ulcer, and when excessive speaks strongly for the latter. Three of his patients vomited about half a litre of extremely acid fluid from the fasting stomach and generally considerable acidity. Kemp in Copenhagen pointed out first that gastric motor insufficiency was also the rule with duodenal ulcers, and Vas's experience is the same. Two of the latter's patients had continuous retention, one considerable retention eight hours after an Ewald test meal, one after six hours, and one after five hours. Three of his six patients without continuous retention had pylorospasm, and all those with continuous retention. He has a record of pylorospasm in only four of his eighty-five patients with gastric ulcer, while it was manifest in seven of his ten patients with duodenal ulcer. In regard to treatment, he says that the same principles apply as to gastric ulcer, only that the hæmorrhage from a duodenal ulcer may be harder to control. Medical measures should be the routine treatment; operative treatment should be instituted only when they fail. He operated on account of stenosis in two cases, for repeated chronic bleeding in another, for results of pylorospasm in three, and for recurrence of symptoms after an at first apparently successful course of medical treatment in three cases. With duodenal ulcer there is less danger of cancer later than with gastric ulcer; cancer of the duodenum seems to be extremely rare.

ON THE BY-EFFECTS OF SALVARSAN.

In Kolozsvár, Dr. Veress held a lecture on the above subject. He said that he used salvarsan in 370 cases, and all but 78 have been kept under supervision. The results of treatment do not indicate, he said, that the salvarsan has much more effectual action on the syphilitic process itself than the usual methods of treatment, while the harmlessness of the drug has by no means yet been demonstrated. In his own experience four of the patients presented serious disturbances on the part of the eyes and three others disturbances in the internal ear. The first patient was a robust girl of 18, and two months after the injection of salvarsan (which had been made two months after

primary infection), she returned complaining of headache, vertigo and impaired vision in the left eye. As the Wassermann reaction was positive, she was given another injection of salvarsan, followed by mercury and iodine, but there has been no improvement in the condition, and the left optic nerve now also shows signs of neuritis. Incipient atrophy of the optic nerve was also discovered in another patient who had seemed to be much benefited by the injection of salvarsan after two years of the usual measures had proved inefficient to cure the malignant syphilis. The treatment had included thirty injections of cacodylate of soda and eighteen of corrosol. Three months after the injection of salvarsan incipient atrophy of the optic nerve on one side became manifest. In the fourth case the syphilis was of five months' standing when the salvarsan was injected, and three months later there were evidences of right peripheral choroiditis with central turbidity of the vitreous body humour. In two of the cases the Wassermann reaction had become negative. Finger and Wechselmann have also reported choroidites, pareses of the ocular muscles and iritis, as remarkable forms of recurrence of the syphilis a few weeks or months after the salvarsan injection. Fischer has reported in 1911 seven papulous iritis in four cases and neurochorioretinitis in another case from two to three months after the injection. All these are occurrences which are never observed under ordinary mercurial treatment in this early stage of syphilis. The same can be said of Finger's three cases, in which the acoustic nerve was affected (described in 1911). Dr. Veress's cases are quite similar to Finger's cases, inasmuch as in one case the infection of the acoustic nerve was complicated with nystagmus, vertigo, and typical tendency to fall, the hearing was intact, indicating that the vestibular nerve had been alone shut off in same way. The symptoms all passed away in a few days, but in the two other cases the trouble was evidently in the true nerve of hearing, and the deafness and vertigo have persisted unmodified to date. In these three patients the Wassermann reaction has been persistently negative, and the auditory disturbances did not develop until from nine weeks to nearly four months after the injection in the case in which they proved transient. Dr. Veress's experience shows that salvarsan has great symptomatic efficiency, but that it does not eradicate the disease.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

NATIONAL INSURANCE ACT.

As was forecasted last week, the decision of the Edinburgh and Leith Division of the British Medical Association was to refuse to work the Insurance Act on the Chancellor's terms. The meeting was very largely attended, and the decision was unanimously arrived at after a short discussion. A number of other Scottish divisions have also met to settle the line of action of their representatives, and with few exceptions find that the proposed terms are intolerable. With regard to sanatorium benefit, the trend of circumstances in Edinburgh is in the direction of placing tuberculosis under the Medical Officer of Health, and arrangements are being made to accommodate a larger number of patients than heretofore in the Edinburgh City Hospital. The actual arrangements as to the administration of sanatorium benefit are, however, far from complete, and the official organisation in Edinburgh cannot at present be compared in effectiveness and comprehensiveness with the voluntary organisation of which the Victoria Dispensary is the centre.

ANTI-VIVISECTIONISTS IN EDINBURGH.

Edinburgh has for a short season had to bear one of the gruesome exhibitions, in the shape of a "vivisection shop," displaying in its windows models of animals, apparatus used in vivisection, posters, etc., which are familiar in some parts of London and elsewhere, but which, hitherto, the northern capital has been spared.

The opening of the shop called forth a strongly worded protest signed by fourteen of the leaders of science here, including Sir William Turner, Sir Thomas Fraser, Professor Schäfer, Professor Lorrain Smith, and others. The letter was supported by remonstrances in the Press, and the shop was closed, but the promoters, evidently on the look out for trouble, hired new premises in Nicolson Street, close to the College of Surgeons, within a stone's throw of the University, almost in the heart of the Medical School. What was only to be anticipated took place. On Friday the shop was raided by about 500 students, who demolished the plate-glass windows, but failed to do any damage to the "exhibits," which had prudently been removed by the proprietors. The police had information that a disturbance was contemplated, and were present in force, so that the disturbers of the peace did not have things all their own way, and in the *mêlée* which ensued 23 arrests were made. The culprits were charged with malicious mischief and breach of the peace at the police court next morning, but trial of the charges was adjourned until Tuesday, the 19th inst. It is, of course, regrettable that an organised attack should be made on anyone, but little sympathy is expressed for the members of the Society which organised the scandalous exhibition. Their folly in opening a shop of this kind in or near a students' quarter is comparable to the conduct of an Orange lodge singing "Boyne Water" in a Catholic district—provocative in the extreme.

BELFAST.

THE INSURANCE ACT.

A MEETING of the medical men of Belfast, convened by the Belfast Division of the British Medical Association, was held in the Medical Institute on Tuesday, November 12th. The chair was occupied by Dr. Gardner Robb, Chairman of the Division, and there was a crowded attendance. Various points connected with the working of the Act were discussed, and the course to be followed was decided. On the question as to whether payment for attendance on tuberculosis patients at home should be by capitation or by a scale of fees for work done, it was decided that pending the extension of medical benefits to Ireland, it should be by a scale of fees. A resolution condemning the action of the nineteen medical men who have not resigned their seats on the Advisory Committee was passed unanimously. Similarly a resolution was passed condemning the action of those medical members of the Local Insurance Committees who have retained their seats after being called upon to resign, such action tending to disunity in the profession, and loss of *esprit de corps*. An urgent appeal was made to all present to support the Guarantee Fund of the British Medical Association, and also to subscribe to the funds of the Conjoint Committee in Dublin. Up till now the Insurance authorities have not recognised the Local Medical Committee, and a resolution asking for recognition, specially in the arrangements for sanatorium work, was passed. The last and most important point discussed was as to what instructions should be given to the representative of the Division to guide him in his voting at the approaching representative meeting, and after full consideration it was unanimously resolved to instruct him to vote against giving medical services under the Act on the conditions at present proposed. Quite a number of Belfast practitioners have in their early days acted as assistants or locum tenens in English towns, specially in Lancashire and Yorkshire, and so are familiar with the conditions of contract practice, and have the warmest sympathy with the men whose whole living depends upon it. Among those who took part in the discussion were the Chairman, Sir John Byers, Drs. John Campbell, R. J. Johnstone, Davison (Ballymena), Rentoul (Lisburn), Thos. Davidson, A. Burns, Cecil Shaw, A. B. Mitchell, and others.

THE SANATORIUM GRANT.

An interesting discussion concerning the position of County Councils in relation to Peamount Sanatorium

and the working of the Sanatorium benefit took place at the meeting of the Tyrone County Council last week. Mr. H. de F. Montgomery moved a resolution to rescind the decision of the County Council to engage three permanent beds in Peamount Sanatorium at a cost of £1 5s. each. He said that though he greatly disliked rescinding resolutions, he thought it his duty to propose this, as the statements made at the former meeting, when this arrangement was agreed to, were misleading. The County Council was under no obligation to provide beds, and the Insurance Committee could act independently of the County Council and send patients anywhere they liked. It had been made perfectly clear by Mr. Birrell's answers to questions, that if they entered into any contract with the owners of Peamount Sanatorium they would become liable for an unknown amount in excess of the figure mentioned in the contract. The statement that twenty-eight county councils had agreed to take beds at Peamount or Rosslare was not true, and he also found that the statement made that the Newcastle (Co. Wicklow) and Forster Green (Belfast) sanatoriums were not approved by the Local Government Boards was not true. He did not wish to be hard on the person who had made these statements, as he had taken service with a hard taskmaster and had to secure contributions from county councils as best he could. The County Council could not prevent the Insurance Committee sending patients where they liked, but they should appeal to them not to compromise themselves by sending patients to either Peamount or Rosslare if they could get beds at Newcastle or at the Forster Green sanatorium, or temporarily at the county hospital. Neither Peamount nor Rosslare was a desirable place.

Dr. Thompson (chairman of the Tyrone Medical Officers' Association) confirmed what Mr. Montgomery had said about Peamount and Rosslare, and strongly recommended the County Council to erect a sanatorium with twenty-five or thirty beds, and to appoint an experienced tuberculosis officer. He assured the Council that if such a scheme were adopted they could rely on the help and assistance of the entire medical profession in the county.

The Council agreed unanimously to rescind the former arrangement, and to go into the whole question again, Dr. Thompson being asked to place his views before a committee appointed to consider it. At this meeting some difficulty has arisen concerning the above-mentioned beds at Peamount. It appears that the secretary of the County Council did not inform the authorities at Peamount of the decision to engage beds, as notice had at once been given to rescind the resolution, but Dr. Irwin, of the Women's National Health Association, had informed them on his responsibility, with the result that two of the beds are already occupied! The County Council authorities say that, not having sent any official notification, they are clearly not responsible for payment.

THE MATERNITY NURSING SCHEME.

Further discussions have taken place on the Maternity Nursing Scheme of the Women's National Association, but it continues to meet with exactly approval. The Armagh guardians decided to refer the matter to a committee, and the Inishowen (Donegal) guardians decided to let the matter drop.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

QUACKERY AND THE NEWSPAPERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In view of the unchanging attitude which *The Times* has for many years assumed towards the quackery question, the leader headed "What is a Quack?" which appeared in a recent issue, can only be fitly characterised as amazing. This leader has been replied to in a letter by Sir Rickman Godlee. It clearly indicates the changed character of that newspaper's facts and arguments.

The article constitutes a new departure, due perhaps to the change in the proprietorship of *The Times*, which, after many rumours, seems now at last to have taken place. The article will certainly be accepted as a kind of apotheosis of unqualified practitioners and nostrum mongers, and we shall see at once a great boom in their trades. I have been, as you are aware, devoting attention to this question for some forty years. For what it is worth, I would now express my opinion that, lacking the support of what is best among the newspaper press, and in view of proceedings in the Law Courts and the General Medical Council during recent years, all chance of legislation to mitigate existing abuses has been destroyed. This may be bad for the profession, but will inflict incalculably greater harm upon the simple, suffering people who have most claim upon the guardianship of the State.

I am, Sir, yours truly,
HENRY SEWILL.

Redhill,
November 13th, 1912.

MALINGERING UNDER THE INSURANCE ACT. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—I wonder whether many of your readers have considered what is likely to be the effect of the Insurance Act with regard to malingering. Judging from what has occurred under the Acts which provide compensation to workmen after injury, the new law seems certain to create a situation extremely awkward for the medical practitioner engaged in working the Act and for the taxpayer who will be called upon to provide the funds. My card and description, which I enclose, will tell you that I have some claim to speak with authority, at any rate in the matter of the Workmen's Compensation and Employers' Liability Acts. A very considerable percentage of cases under these Acts are undoubtedly either cases of exaggerated claims or of pure shamming. Surgical injuries for the most part are easily recognisable; there is very little room for mistake or pretence in, for instance, such things as fractures, or dislocations, or herniæ, or injuries to the eyes. But even after reduction of a simple dislocation, and lapse of enough time for the joint to recover, I have seen a large number of cases in which I was tolerably certain, although perhaps unable to be positive, that the weakness and pain of which the patient complained, and which he asserted prevented him from working for weeks or months, were either entirely non-existent or grossly exaggerated. The difficulty of forming a positive diagnosis increases, of course, when the patient complains of illness, not injury; and these will be the awkward cases under the Insurance Act. It will be impossible for the practitioner in numerous instances to keep the cases under sufficiently close observation and to carry out a process of scientific examination needed to clear up the diagnosis. It will be an extremely uncomfortable or disastrous thing for him if he certify a really deserving case as an imposture; and the justifiable course in many instances will be to give the applicant the benefit of the doubt. If only a small percentage of malingering cases from among the 14,000,000 of insured persons occur annually it may mean an expenditure which has not been contemplated, and which may easily run into hundreds of thousands of pounds a year.

I am, Sir, yours truly,
A LANCASHIRE DOCTOR.

Manchester,
November 9th, 1912.

PHTHISIS: A NEW REMEDY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—Before thousands upon thousands are spent on sanatoria for consumptives, I should like a few thousands of my medical brethren to test my new discovery. I have been for the last few years using something which has never been thought of or tried before—viz., lysol. I have been using it in the early stages of tuberculosis, first in inunctions, then fine spray vapour inhalations, and now hypodermically, thus:—

Lysol (pure), one drachm.

Aq. distillat., two ounces.

Makes about a 3 per cent. solution.

One drachm of this to be injected under the skin around the chest once or twice daily, to be increased every three or four days by 1 per cent. until 15 per cent. is reached. Its effect will be soon seen. If it causes any slight uneasiness add to each ounce of solution when used, cocaine hg. $\frac{1}{4}$ gr. When 15 or 20 per cent. is injected at each time it should be once a day. I have never exceeded the latter, and each puncture should be an inch from the former one. One will have to use his own discretion as to what percentage he uses and its effect on the patient. Those who test it should give it a fair trial and make known the results through your columns. I think at least a three months' course would show up fully its wonderful effects.

I am, Sir, yours truly,
J. W. LANE, M.D., B.Ch.

Keyham, Devonport,
November 18th, 1912.

OBITUARY.

DR. MENZIES, EDINBURGH.

THE death was announced on the 11th inst. of Dr. David Menzies, a well-known practitioner in Edinburgh. He graduated in 1876 and shortly thereafter became associated in practice with his father, who had one of the largest practices in Edinburgh. Dr. Menzies was of a retiring disposition and took little part in the actual work of any of the professional societies in Edinburgh. In his younger days he was an officer in the City Artillery, and as his chief recreations he enjoyed shooting and golf. As he succeeded to his father's practice, so is he now followed by his eldest son. Dr. Menzies had been ailing since the beginning of the year.

DR. GEORGE TAYLOR GUILD, DUNDEE.

THE death occurred on the 15th inst., after a few days' illness, of Dr. Taylor Guild, at the comparatively early age of 44 years. Dr. Guild graduated at Edinburgh in the early nineties, and after a short experience of practice turned his attention to laryngology, which he studied in Marburg and Vienna. Thereafter he began the practice of his speciality in Dundee, where he rapidly acquired the confidence of his *confrères*, and was elected to the staff of the Dundee Infirmary. He was also lecturer on laryngology at the Dundee Medical School. Dr. Guild had under a quiet, reserved manner a great deal of natural humour and a kindly, generous disposition. His death is much regretted among his friends and acquaintances. He is survived by a widow and two children.

REVIEWS OF BOOKS.

PUERPERAL FEVER AND ALLIED INFECTIOUS DISEASES. (a)

THE author endeavours to prove that puerperal infection is largely, if not entirely, due to contamination, directly or indirectly from suppurating wounds, and therefore that the high puerperal morbidity in manufacturing and mining districts is explained by the high accident rate in these districts. To support his thesis he gives a number of highly instructive tables of population, cases of puerperal fever, and the proportion of practitioners and midwives attending the cases. The bulk of the figures refer to Lancashire. Treating auto-infection as an extremely rare occurrence, he maintains that the person conducting the case is the real source of infection. Accidents are common in mining centres, and practitioners must be constantly dressing septic cases and so becoming involuntarily carriers of septic material. Unless very careful in their methods of disinfection they are liable to infect their obstetric cases. The high incidence of puerperal

(a) "Statistics of Puerperal Fever and Allied Infectious Diseases." By George Geddes, M.D., C.M. (Aber.). Pp. 119. Bristol: John Wright and Sons, Ltd. 1912. Price 6s. net.

fever in such districts is strikingly brought out in some of the tables. The coal strike of 1912 is used to support his claims. During March and April there were hardly any accidents in mining districts, and the number of cases of puerperal fever dropped much below the average; while at the same time in other districts it remained the same. Hospital statistics have been greatly improved, but those of general practice are still very disheartening. This book can be warmly recommended as a thoughtful contribution to the solution of a serious problem.

THE CARE OF CHILDREN. (a)

We learn from the preface that this little book is intended to offer to newly qualified practitioners and to mothers and nurses some practical advice on the everyday care of children at the nursery age. It is seldom our pleasure to come across such a practical manual as this. Dr. Brockbank writes out of his own experience of infants, and his remarks throughout bear evidence of close and accurate observation of the infant's ways. He admits that teething does cause trouble even in healthy babies. He also states, what we have been endeavouring to impress on the profession for years past, that increase of weight may not necessarily be a true index of the healthy progress of the baby. There is no attempt made to give prescriptions for drugs, as these, he rightly states, concern the doctor only. Altogether this is a delightfully written book, and one which contains just the right sort of information for the practitioner who has had no practical experience of nursery management and the care of infants.

MEDICAL NEWS IN BRIEF.

The National Insurance Act.

At a meeting of the Joint Committee of the Royal Colleges of Physicians and Surgeons, the Society of Apothecaries, and the Medical Faculties of the Universities of England, held at the Royal College of Physicians last week, the following resolutions were passed:—

(1) "That in the opinion of this Committee the conditions set up by the Provisional Regulations of the Insurance Commissioners, dated October 1st, 1912, are of such a nature as to interfere injuriously with the right and proper independence of the medical profession, and with efficiency in the treatment of insured persons."

(2) "That medical practitioners, in matters concerning their professional conduct, ought not to be tried before a tribunal that is not professional, the decisions of which may have the most serious effect on their reputation and practice."

(3) "Seeing that the carrying out of the Provisional Regulations is left largely in the hands of the Local Insurance Committees, it would be unwise to agree to accept them (even if otherwise satisfactory), so long as the insured persons are represented upon these Committees by an overwhelming majority."

(4) "That attention should be called to the advisability of establishing tuberculosis centres in connection with those hospitals to which medical schools are attached."

At a meeting of the Executive Committee of the Imperial Medical Reform Union, held on the 7th inst., it was unanimously resolved:—"That the Executive Committee of the Imperial Medical Reform Union consider that the members of the profession can be recommended to accept service under the Insurance Act on the following conditions:—(1) That payment be made for actual services rendered and medicines supplied; (2) that the income limit of forty shillings a week be observed; (3) that the conditions of service be compatible with the honourable traditions and practice of the profession; and (4) that the whole ques-

tion of remuneration be reconsidered at the end of three years."

Dublin Professors and Medical Benefits.

A MEETING of the Dublin Division of the Leinster Branch of the British Medical Association was held last Thursday in the College of Physicians, Kildare Street. The object of the gathering was to consider a report of Council to Divisions and the representative body on the position of the profession in relation to the National Insurance Act, but with especial reference to the latest statement of the Chancellor of the Exchequer with regard to the increased remuneration for medical benefit. The attendance was large and representative, and after somewhat prolonged deliberation the following resolution was adopted:—

"That this Division is of opinion that the concessions granted, though considerable, are not yet such as to justify the medical profession in accepting service under the Act, as it now stands."

London (Royal Free Hospital) School of Medicine for Women.

The annual dinner of the Royal Free Hospital and School of Medicine for Women will be held at the Trocadero Restaurant, Piccadilly Circus, on Wednesday, December 11th, at 6.45 p.m. for 7.15 p.m., at which Mr. Stanley Boyd will take the chair. Applications for dinner tickets (7s. 6d.) should be sent to the Hon. Secretaries, Dr. Winifred Cullis, D.Sc., 8 Hunter Street, Brunswick Square, W.C., and Dr. Frederick Langmead, M.D., 53 Queen Anne Street, W., not later than Saturday, November 30th.

Sanatorium Destroyed.

THE Queen's County Sanatorium for Consumptives, in the grounds of the County Infirmary at Maryborough, was totally destroyed by fire last Sunday. The outbreak is stated to have originated in a private apartment of a nurse, who was then absent at Mass in the parish church. The original cost of the erection and equipment of the sanatorium was about £1,000, and the damage is stated to be covered by insurance. The building was erected by public subscriptions, collected mainly through the exertions of Lady Cote, President of the Queen's County branch of the Women's National Health Association. The foundation stone was laid by Lady Cote on September 28th, 1910, and in the May following the Sanatorium was formally opened by Lady Aberdeen.

The Harveian Society of London—Annual Dinner.

THE annual dinner of the Harveian Society of London was held at the Hotel Great Central on November 14th, the President, Dr. H. J. Macevoy, in the chair. After the usual loyal toasts, the President proposed the health of the Harveian Society, and Mr. D'Arcy Power proposed "The Kindred Societies," which was responded to by Mr. A. H. Tubby, President of the Hunterian Society. The toast of "The President" was proposed by Dr. Willcox, and Dr. Macevoy, in his reply, said he wished to acknowledge the assistance he had received from the secretaries, Dr. Carmalt Jones and Dr. Turtle, and proposed their healths. Between the toasts an excellent programme of music, arranged by Mr. Vivian Bennetts, was performed, including songs by Mr. Herbert Tracey, Mr. Wilden Knight, and Miss Maude Willby.

Domiciliary Treatment of Consumption.

A DEPUTATION from the Dublin Insurance Committee waited last Friday on the Irish Insurance Commissioners with reference to the question of domiciliary treatment of people who suffer from consumption. The deputation consisted of Dr. Rowlette, Mr. Kelly, Miss Gargan, and Dr. M'Walter.

The Countess of Aberdeen, who was not able to be present, sent an apology.

The deputation pointed out to the Commissioners that they considered the Act useless as far as combatting tuberculosis was concerned, unless the Committee had power to give nourishment.

Mr. Glynn, Chief Commissioner, speaking for the Commissioners, stated that their difficulty was that it might lead to abuse if the Committee had the power to give nourishment; but if the Committee could arrange with the Dublin Corporation or some such body as

(a) "Children: Their Care and Management." By E. M. Brockbank, M.D. Viet., F.R.C.P., Honorary Physician, Royal Infirmary, Manchester. London: Henry Frowde and Hodder and Stoughton, 1912.

that to give the domiciliary treatment, including nourishment, he thought it probable that such a scheme would be approved of. He thought the Corporation had that power under the Act.

Dr. Rowlette asked whether the Insurance Committee could not themselves make grants to institutions that would feed patients.

Mr. Glynn said he thought they had that power, but they (the Commissioners) were advised that there should be no separation of treatment—that is to say, that the same body should supply doctors, nurses, drugs and nourishment.

The Corporation of Glasgow and Treatment of Consumption.

THE Health Committee of Glasgow Town Council have considered the question of the treatment of tuberculosis, and to give coherence to the scheme that has been prepared, recommend that the Medical Officer of Health, Dr. A. K. Chalmers, be formally appointed Administrative Tuberculosis Officer; that his assistant, Dr. A. MacGregor, be appointed Supervising Tuberculosis Officer, at a salary of £500; that five additional nurses be appointed to the various dispensaries; and that the Medical Officer of Health be authorised to appoint three assistant tuberculosis officers to take charge of various dispensaries. Two wards at Ruchill Hospital are to be used for a year for the treatment of consumption, sanction for that arrangement having been received from the Local Government Board.

Royal College of Surgeons of England.

At the Primary Fellowship Examination in Anatomy and Physiology, held on November 7th, 8th, 12th, 13th, 14th and 15th, 116 candidates presented themselves, of whom 22 per cent. were approved and 78 per cent. were rejected. Among the successful candidates were the following:—Benjamin Biggar, M.R.C.S., L.R.C.P., John B. Stanley, M.R.C.S., L.R.C.P., Andrew R. Bearn, M.D., B.Ch. Edin., Alec A. Lees, B.A.Cantab., John B. Haycraft, M.B., Ch.B. Edin., James C. Brash, M.A., B.Sc., M.B., Ch.B. Edin., Robert A. Kerr, M.B., B.Ch., B.A.O., Donald Watson, M.B., Ch.B. Edin., Vraspillai Gabriel, L.M.S., M.R.C.S., L.R.C.P., Geoffrey C. Linder, Abraham S. Liebson, B.A., Ernest C. Bradford, B.A. Cantab., Edwin D. Pullon, B.Sc., M.B., Ch.B. Edin., Martin W. K. Bird, B.A.Cantab., John O. Thomas, Dudley D. Pinnock, M.B., B.S. Melbourn, M.R.C.S., L.R.C.P., John W. Tonks, B.A.Cantab., M.R.C.S., L.R.C.P., Frederick J. Anderson, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Matthew W. B. Oliver, M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Philip S. Foster, M.B., Ch.B. Otago, M.R.C.S., L.R.C.P., Stanley E. V. Brown, M.B., Ch.B. Otago, M.R.C.S., L.R.C.P., Rhys T. Jones, B.Sc., Alan C. Perry, Sydney H. Hodges, Samuel W. M. Jones, and Gilbert C. Chubb, M.B., B.S., D.Sc. Lond., M.R.C.S., L.R.C.P.

New Members Admitted.—At an ordinary meeting of the Council of the Royal College of Surgeons on the 14th inst., with Sir Rickman J. Godlee, President, in the chair, the following candidates were admitted members of the College:—A. Ashmore, E. Bach, H. R. Bastard, G. E. Beaumont, B.A. Oxon., P. L. T. Bennett, L. G. Bourdillon, R. St. L. Brockman, B.A. Camb., R. G. Brown, E. N. Butler, B.A. Camb., L. T. Challenger, P. C. Cole, L. G. Crossmann, K. F. R. Davison, A. E. L. Devonald, G. R. Dobrasnain, S. Doraisamy, F. N. Doubleday, L.D.S. Eng., F. P. Duncan, W. J. I. Dwyer, T. L. Ellis, M. S. Esler, B. C. Ewens, B.A. Camb., E. G. Fisher, B.A. Camb., W. B. Foley, W. K. Fry, V. Gabriel, G. E. Genge-Andrews, D. M. Gibson, E. A. M. J. Goldie, R. S. Graham, J. Greene, M. J. Haffey, D. B. I. Hallett, W. J. Hart, B.A. Oxon., H. Harvey, L.D.S. Eng., H. J. B. Heelas, C. Helm, B.A. Camb., H. J. Hoby, R. J. Horton, D. E. J. S. Hughes, A. Jackson, B.A. Oxon., E. B. Jardine, D. D. B. Jay, B.A. Camb., H. W. Jones, R. A. Jones, L.S.A., S. Keith, C. Kennedy, W. J. T. Kimber, G. A. M. Leopold, T. P. Lewis, J. B. Lowe, W. C. D. Mails, B.A. Camb., L. A. Martin, G. O. Maw, B.A. Camb., M. Mehta, R. H. Miller, G. W. Mitchell, B.A. Camb., S. G. Papadopoulos, S. G.

Platts B.A. Camb., E. G. Reeve, W. R. Reynell, B.A. Oxon., J. F. G. Richards, I. Ridge-Jones, G. H. Roberts, W. Robinson, H. C. Rook, G. A. Russell, C. M. Ryley, R. Saravanamuttu, F. R. Scott, A. S. Seabrooke, B.A. Camb., H. N. Sealy, B.A. Camb., W. J. D. Smyth, B.A. Camb., L. B. Stringer, A. L. Sutcliffe, B.A. Camb., W. F. Thomson, B.A. Camb., H. E. Thorn, D. B. Truman, C. R. V. von Braun, J. R. Waddy, G. A. Walker, H. Walker, M. H. Watney, B.A. Camb., W. G. Watson, B.A. Camb., W. L. Webb, H. N. Webber, B.A. Camb., A. Wilson, E. Wordley, B.A. Camb., A. M. Zamora.

A. G. H. Lovell, M.B., L.R.C.P. Lond., was admitted a Fellow of the College.

The following candidates were admitted Licentiate in Dental Surgery:—H. H. Bond, E. L. Z. Fickling, W. W. Miron, E. V. B. Turner, and T. B. Tustian.

E. S. Marshall, L.R.C.P., M.R.C.S., St. Bartholomew's and London School of Tropical Medicine, was granted the Diploma in Tropical Medicine, which is issued jointly with the Royal College of Physicians.

The President reported that the Bradshaw Lecture would be delivered by Mr. C. Mansell-Moullin, F.R.C.S., on December 5th, and that the subject of the lecture would be "The Biology of Tumours."

National University of Ireland.—University College, Cork.

A MEETING of the University for the Conferring of Degrees was held on Saturday, November 2nd. The following Degrees were conferred:—

M.E. Degree.—Frederick F. Burrows, B.E., First Class Honours (*in absentia*); James H. de W. Waller, B.E., First Class Honours.

M.B., B.Ch., B.A.O. Degrees.—Patrick J. Walsh, Second Class Honours on whole examination; William F. O'Regan, Second Class Honours on whole examination; Maurice J. Roche, First Class Honours in Midwifery and Gynaecology; Stanley P. Stoker, Second Class Honours in Medicine.

Pass.—Daniel J. Barrett, Robert Harrington, John F. Hill, Thomas Hill, Denis Lynch, Patrick C. O'Donnell, Eileen M. O'Keefe, John F. Rahilly, James J. Ryan.

M.D. Degree.—Pass: Joshua Keyms, B.A., M.B., B.Ch., B.A.O.

Diploma in Public Health.—Jeremiah Reidy, M.B., B.Ch., B.A.O. (*in absentia*).

Trinity College, Dublin.

The following candidates have passed the Intermediate Medical Examination, Part 1., Michaelmas Term, 1912:—Sydney W. Fisher, David R. Hennessy, Douglas C. Pim, Godfrey Bateman, Herbert Mitchell, Arthur G. Fisher, Edward Mannix, Francis A. McHugh, Edmond Robinson, Andrew W. P. Todd, George O. F. Alley, David S. Martin, Henry S. Campion, James E. Jameson.

Institutes of Medicine.—Frederick R. S. Shaw.

Final Medical Examination, Part II.—Medicine.—Walter Crane, Marjorie Chapman, William O. W. Ball, Arthur P. Draper, Henry B. F. Dixon, William Frier, Eric C. Crichton, Brian D. Crichton, Hubert T. Bates, Edwin S. Johnson, Georgina Revington, Leonard Shiel, William J. Stewart, Jane F. Colquhoun, Patrick Murphy, William P. Croker, Kenneth K. Drury, Frederick B. McCarter, Edwin F. O'Connor, Charles W. C. Myles, Hedley Boyers, and Robert Hemphill.

Conjoint Examinations in Ireland.

THE following candidates have passed the examination by the Royal College of Physicians and the Royal College of Surgeons, November, 1912:—

Diploma in Public Health.—David Adams, F.R.C.S.I., James M. Bennett, L.S.E., L.R.C.P.I., Captain Leonard Bousfield, M.D. Cantab., R.A.M.C. (with honours), John Burke, L.R.C.P. and S.I., William H. Date, L.S.A., M.R.C.S., Marks Golding, L.R.C.P. and S.I., Miss Alice W. Maclean, M.B., Univ. Glas., Albert E. S. Martin, F.R.C.S.I., Alfred S. Millard, M.B., Univ. Edin., William M. Morison, L.R.C.P. and S. Edin., Robert M. Wishart, L.R.C.P. and S. Edin.

NOTICES TO CORRESPONDENTS, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

Dr. P. G. (Berlin) is thanked for his letter, but we regret that our "Exchange List" is already so full that we cannot further add to it.

Mr. H. S. L. (Manchester).—Your first question may be answered by the reply that it is "Aspirin" under another designation. For reply to your second, we must refer you to "Secret Remedies," which can be purchased through any bookseller, and in which you will find an analytical report of those much advertised "Pink Pills" and "Doan's Backache Pills."

WORKMEN'S COMPENSATION ACT, 1906.

THE Home Secretary asks us to give notice that in consequence of the resignation of Dr. Herbert Hawksworth, the appointment of the Medical Referee under the Workmen's Compensation Act, 1906, for Llanfyllin and Welshpool County Courts will be vacant as from December 31st next. Applications for the post should be addressed to the Private Secretary, Home Office, London, and should reach him not later than December 11th, 1912.

CUNICULUS.—We have made the necessary inquiries of two leading veterinarians, and find that nothing is known regarding rabbit virus. Virus for the destruction of rats, however, has been extensively used.

THE WALL AUTO-WHEEL.

ONE of the most interesting exhibits at the forthcoming Cycle Show at Olympia, November 25th to 30th, and one which will appeal strongly to medical men, is a novel form of motor bicycle known as the Wall Auto-wheel. It consists of a cleverly-designed, self-contained, auxiliary unit, in the shape of a one-wheel motor, of one horse-power, which is simply clamped by a connecting frame to the back hub spindle of an ordinary bicycle, no structural alterations of any kind being required. The running is quiet, the steering simple, and speeds of 6 to 20 miles can be obtained unaided along level roads. The machine is neat in appearance and it remains upright when at rest. The price is only 16 guineas. Medical men to whom this form of locomotion is a necessity or an attraction should certainly visit the stall of the International Auto-Wheel Co., Ltd., at Olympia next week.

Dr. T. L. S. (London, N.).—The recent researches of Nagelschmidt show that the alternating electric current may be modified in such a way that it affects the central nervous system in the same manner as Leduc's interrupted current, only the action is more powerful and more under control. It is unlikely, in the present state of our knowledge of electro-therapeutics, that such methods for producing sleep will become at all general.

"INSTINCT."

THE play now running at the Duke of York's theatre has a great interest for the medical profession. Charles Frohman presents "Instinct," a play written by Henry Kistemaekers, and translated for the English stage by Pontyn Stanlows. This play deals with the possibility of the professional instinct of a doctor prevailing over the personal feelings that may exist in his mind towards an individual. Dr. Mandover (played by C. Aubrey Smith) arrives at a point in his life where he has an opportunity of saving the life of a man whom he believes to be his wife's lover, or leaving him to bleed to death. The story surrounding the lives of Dr. Mandover and his wife (Miss Lilian Braithwaite) is told in three acts and supplies a very good evening's entertainment.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 20th.

ROYAL SOCIETY OF MEDICINE (SECTION OF THE HISTORY OF MEDICINE) (1 Wimpole Street, W.).—5 p.m.: Election of Officers and Council. Papers by Sir William Osler, Bart., F.R.S., Dr. Raymond Crawford, Mr. D'Arcy Power, Dr. Michael Foster. An Exhibition of Pictures showing the Evolution of the Microscope will be on view.

BROMPTON HOSPITAL FOR CONSUMPTION.—4.30 p.m.: Lecture by Dr. Jex-Blake.

THURSDAY, NOVEMBER 21st

ROYAL SOCIETY (Burlington House, London, W.).—Mr. A. S. Russell, Mr. R. Rossi, Mr. J. A. Gray, Mr. J. C. Chapman, Mr. W. Wahl, Mr. R. E. Siade, Mr. F. D. Farrow, Mr. A. Russell.

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1 Wimpole Street, W.).—5 p.m.: Cases by Dr. J. H. Sequiera, Dr. A. Castellani, and others.

ROYAL SOCIETY OF MEDICINE (SECTION OF NEUROLOGY) (1 Wimpole Street, W.).—8 p.m.: Clinical Meeting: Cases by Dr. Turner, Dr. Batten, Dr. Buzzard, Dr. Fearnsides, and others.

ROYAL SOCIETY OF MEDICINE (1 Wimpole Street, W.).—8.30 p.m.: Special Meeting. Discussion opened by Dr. H. G. Adamson.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—3 p.m.: Annual General Meeting of the Fellows and Members. Sir Victor Horsley, F.R.C.S.Eng., will move this resolution: "That this Twenty-eighth Annual Meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council of the College, which as now constituted only represents those Members who also hold the Fellowship; and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation," supported by Dr. J. Oldfield, Dr. Joseph Smith, J.P., President of the Society, and others. Dr. W. G. Dickinson (Hon. Sec. for fifteen years) will move: "That this Meeting regrets that the Council has not

called a Special General Meeting of Fellows and Members to consider the National Insurance Act, 1911."

HARVEIAN SOCIETY OF LONDON.—8.30 p.m.: Dr. A. M. Gossage, Mr. W. H. C. Greene.

FRIDAY, NOVEMBER 22nd.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASES IN CHILDREN) (1 Wimpole Street, W.).—4.30 p.m.: Cases by Dr. Bunch, Dr. J. W. Carr, Dr. Eric Pritchard, Mr. L. E. C. Norbury, Mr. H. A. T. Fairbank and others. Specimens by Dr. C. Paget Lapage and Dr. J. D. Rolleston. Paper by Dr. Leonard Guthrie.

ROYAL SOCIETY OF MEDICINE (SECTION OF EPIDEMIOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Papers by Dr. R. J. Ewart and Dr. F. G. Crookshank.

MONDAY, NOVEMBER 25th

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Clinical Evening. Cases will be exhibited by Sir W. Watson Cheyne, Bt., C.B., F.R.S., Drs. Palmer, Poynton, and Messrs. Paul B. Roth, Willmott Evans and others.

Appointments.

BREBNER, C. S., M.D.Edin., D.P.H.Camb., Medical Officer of Health to the Chiswick Urban District Council.

DAVIES, G. MEREDITH, M.B., B.S.Lond., Resident Medical Officer at the British Lying-in Hospital.

FOTHERGILL, W. E., M.D.Edin., Joint Lecturer in Obstetrics and Gynecology in the University of Manchester.

LATON, T. B., F.R.C.S.Eng., Throat and Ear Surgeon to Guy's Hospital.

WALLS, W. K., M.B.Lond., Lecturer in Clinical Obstetrics and Gynaecology in the University of Manchester.

Vacancies.

Monsall Fever Hospital, Manchester.—First Assistant Medical Officer. Salary £200 per annum, with board, lodgings, and washing. Applications to the Chairman of the Sanitary Committee, Public Health Office, Civic Buildings, 1 Mount Street, Manchester.

Coventry Education Committee.—Assistant School Medical Officer. Salary £300 per annum. Applications to Fredk. Horner, Secretary, Education Office, Coventry.

Royal City of Dublin Hospital.—Ophthalmic Hospital. Immediate application to Hon. Secretary of Medical Board. (See advt.)

Enniskillen Union.—Lisbellaw Dispensary District.—Medical Officer. Salary £90 a year, and £6 as Medical Officer of Health, together with registration and vaccination fees. Immediate application to R. Wilson, Clerk of the Union. (See advt.)

Births.

BARWELL.—On Nov. 12th, at 55 Wimpole Street, the wife of Harold S. Barwell, F.R.C.S., of a son.

DAVIDSON.—On Nov. 13th, the wife of Dr. Duncan Davidson, M.D., 15 Priory Row, Coventry, of a daughter.

EDE.—On Nov. 9th, at 5 College Yard, Worcester, the wife of W. E. Moore Ede, M.D., of a son.

EWART.—On Nov. 15th, at the Broadgates, Gullane, N.B., the wife of Edward Ewart, M.D., of a son.

GLANVILLE.—On Nov. 11th, at Emsworth, Hants, the wife of L. S. Howard Glanville, M.D., B.S., of a daughter.

HENDERSON.—On Nov. 13th, at The Red House, Amersham, Bucks, the wife of Dr. Hal J. Henderson, of a son.

MUSSEN.—On Nov. 13th, at 13 Abercromby Square, Liverpool, the wife of Dr. A. A. Mussen, of a son.

RUSSELL.—On Nov. 12th, at Osman House, Fortis Green, East Finchley, N., the wife of J. Dill Russell, B.S.Lond., F.R.C.S.Eng., of a son.

Marriages.

BENSON—WISHAW.—On Nov. 11th, at Kilmersdon Parish Church, John B. Benson, F.R.C.S., of Circus House, Bath, to Enid, sixth daughter of Mr. and Mrs. James Wishaw, of Charlton House, Kilmersdon, and St. Petersburg.

JOHNSTON—HONEYMAN.—On Nov. 12th, at St. George's Church, Hanover Square, Lt.-Colonel C. A. Johnston, I.M.S., son of the late William Johnston, of Madras, India, to Isabel Mary, eldest daughter of the late Dr. J. H. Honeyman, of Auckland, New Zealand, and Mrs. Bruce-Porter, of 6 Grosvenor Street.

Deaths.

ARMSTRONG.—On Nov. 15th, at Somersset House, Chine Road, Bourne-mouth, George William Armstrong, Surgeon, late of Royal Hospital Schools, Greenwich, aged 72 years.

ATKINSON.—On Nov. 17th, at Crewe, suddenly, Dr. James R. Atkinson.

CONOLLY.—On Nov. 11th, at Madeira, Beaumont Bowley Conolly, M.R.C.S., formerly Lieutenant of the 72nd Regiment, Duke of Albany's Own Highlanders (third son of the late Captain Conolly, of the Royal Engineers), the beloved husband of Mrs. Helen Conolly, of the "Quinta Pimenta," Funchal, Madeira, aged 70.

DRANT.—On Nov. 15th, at Terrycot, Crouch Hill, N., Margaret, the beloved wife of James John Durant, Lt.-Colonel, I.M.S.

McLoughlin.—On Nov. 8th, at University College Hospital, Captain Wilfred Montagu McLoughlin, late R.A.M.C., youngest son of the late Lieutenant-Colonel John McLoughlin

O'Connor.—On Nov. 15th, at Coolavin, Chatteris, Martin O'Connor, M.R.C.P.I., aged 74.

No. 22.

NOTES AND COMMENTS.

Insurance Points.

THERE are certain points in the latest stage of the Insurance Act dispute which will be endorsed by most medical men. First and foremost, let us have the precise sum that is to be allotted free of all deductions—why should a man be paid for his professional services by a sum that has a fluctuating margin?—if so much money is not wanted for extra drugs and so on, it may go to the doctor. Is there any official service in the Kingdom remunerated in this unsatisfactory fashion? It is as if one were to say to a workman, Your wages have a margin of 2s. 6d. with which you can buy food, but 1s. 6d. of that sum may be wanted to pay for tools in another part of the workshop; if not so wanted, it will come to you. What employer would offer, or what workman would accept so meticulous an offer? Then there is mileage. Why should a man whose practice lies in a thinly populated district be compelled to present the Government with the time, labour, and cost of his journeys to outlying patients. Mr. Lloyd George is probably beginning to realise more accurately the real volume and weight of medical opposition to the Act.

MEANWHILE, Dr. Esmonde, M.P., has published another scheme, asking medical men to sign the agreement for three years' service, on condition that the following terms are granted:—1. Capitation fee of 8s. 6d. (excluding tubercular and venereal disease) to cover visits and medicine (other than serum treatment), from 9 a.m. to 9 p.m. 2. Free choice of doctors where possible. 3. Limit of 1,500 patients. 4. Complaints to go to local committee of medical men; appeals, to a board of medical and of lay members. Dr. Esmonde says he has hundreds of answers from medical men willing to work the Act under his conditions. The income obtainable from 1,500 patients at 8s. 6d. per head is, roughly, £600 per annum. Dr. Esmonde's views are worth careful consideration, as he has gone through many years of the rough-and-tumble of general practice, but we fail to see that he has made any solid contribution towards solving the vexed problem. He has shown that there are some hundreds of medical men ready to act independently of their brethren, but, unhappily, that is no news. We welcome his attitude as genuine, however much we may hesitate in accepting his conclusion. It is with far other feelings, however, that we find a well-known specialist bewailing in the London newspapers the spirit of trades-unionism that pervades the medical profession. Whatever the issue of the present strife, the one great feature emerg-

ing from the noise and din of conflict is the collective enthusiasm—call it trades-unionism if you will—that has inspired and rendered possible the defence of our interests as a profession.

Alcohol at Sunrise.

THE Birmingham Licensing Committee have put forward a series of proposals with a view of advancing the sobriety of their town. Amongst other things, they suggest that the opening hour should be changed from 6 a.m. to 8.30 a.m. This seems to be a step of the right kind in practical temperance legislation. Who but a toper recovering from his overnight potations could want beer or spirits at six o'clock in the morning? By some sort of Nemesis the first beer drawn in the morning has long been known to cause plumbism owing to its action upon the lead pipes in which it has lain during the night. Postponing the hour would not, of course, lessen this particular risk. Nor would the alcohol swallowed at 8.30 a.m. be less fatal than that taken two hours and a half earlier, but it may be presumed there would be less opportunity of indulging at the later hour. But, of all drinking, that of the morning is the most harmful, and of all morning drinks that which is taken in the early hours on an empty stomach. No reasonable individual should want alcohol except at, say, dinner or supper, and for that there is no necessity. To drink before evening or between meals is a silly habit that steals away a man's strength both of body and of mind. We are glad to learn that the Birmingham magistrates approved the proposed change from 6 to 8.30 in the morning by a substantial majority.

Alcohol after Sunset.

THE same magistrates gave their unanimous approval of a second recommendation of the Licensing Committee to the effect that no woman or person under sixteen should be served with intoxicating liquor for consumption either on or off the premises before noon. The reasons for this proposal are fairly self-obvious. The magistrates, however, were not inclined to fall in with all the views of the Licensing Committee, for they rejected the crucial proposal that the closing hour should be changed from 11 until 10. There is a good deal to be said in favour of the proposal, as well as something on the other side. Broadly speaking, most people would be able to get all the alcohol they want before 10 o'clock, if such a rule were in force, just as now they do so by 11, or in London by midnight. The drinking habits of the nation have decreased greatly during the past generation, but it will probably require many years before liquor legislation can be reduced to a really reasonable and at the same time

just and equitable basis. Other points, such as Sunday opening and grocers' licences, remain to be considered by the Birmingham magistrates.

OUR attention has been drawn to a **Public Health and Medical Practitioners.** query form which the Public Health Department of Dublin has recently addressed to medical practitioners who notify a case of infectious disease. The medical man is invited to express opinions, for the assistance of the medical officer of health, on the possible cause of the disease. He is asked to state, for instance, whether he considers it due to any article of food, such as milk or shellfish, or to bad drainage. Further, he is asked, "Do you wish any enquiry made which would throw light on the cause of the disease?" We do not know whether other health authorities adopt similar measures, but the whole procedure seems to us objectionable from sundry points of view. It is an attempt to throw on the private practitioner the responsibilities properly resting on the department of public health. It is the duty of the department to make full enquiries into the causes of an outbreak of illness, and that such enquiries should only be made at the wish of a private practitioner—as the above query suggests—is a relegation of duty. It should be clearly understood that when a practitioner has notified a case of infectious disease his duty to the public health authority is at an end. To ask him to answer a number of questions on a professional matter without proffering a fee is to expect him to do for nothing what the officers of the department of public health are paid for doing. Moreover, to furnish the information asked might very readily expose him to an action for damages. We advise medical men who may receive the document in question either to ignore it altogether, or to demand a suitable fee for supplying the information requested.

LEADING ARTICLES.

THE NATIONAL INSURANCE ACT AND THE MEDICAL PROFESSION.

THE latter part of last week witnessed the rejection of the terms offered by Government for the administration of medical benefits under the National Insurance Act. The importance of this step, so far as the medical profession of the United Kingdom is concerned, it would be difficult to over-estimate. It amounts to a declaration of war. It registers a collective decision on the part of the medical profession, which is thereby committed to a policy that practically reaffirms the famous cardinal principles advanced at an earlier stage of the controversy. There is little need to go over the familiar ground: the income limit; the free choice of doctor; the administration of medical benefit; the method and amount of remuneration, and the rest. It is sufficient to know that the conditions offered by the Chancellor of the Exchequer, in spite of the various modifications which have been added to those of the original Bill, have been rejected by the great majority of the medical profession as represented by the Representative Meeting of the British Medical Association. The refusal of present conditions of service was carried by an overwhelming majority in the following terms:—

"That in the opinion of this Representative Meeting the Regulations issued by the Insurance Commissioners and the latest proposals of the Chancellor of the Exchequer are unworkable, derogatory to the profession, and a positive danger to national health. As a consequence, the medical profession declines to undertake service under the Act and Regulations as at present constituted."

That clinches the matter so far as the cardinal principles are concerned, but happily the door is not closed to further negotiations. It was resolved that the result of the meeting be communicated to the Chancellor of the Exchequer, with a suggestion for a conference upon the points which the representatives regarded as the reasonable demands of the medical profession. It is, of course, impossible to forecast the outcome of the struggle that has been forced upon medical men, but it is encouraging to find that they are able to defend their legitimate interests with an organisation and a loyalty that has so far proved equal to the occasion. Meanwhile it is interesting to observe the effect of what may be regarded as practically an ultimatum upon our friends the enemy. For this purpose we select an article from the *Daily News and Leader*, which throughout these negotiations has shown a bitterness against the medical profession which it is difficult to explain on any other ground than that of the virulence of political bigotry that can see one side only of its cherished projects. If the medical men find their practice suddenly turned topsy turvy and their livelihood jeopardised by a Radical Act of Parliament, any protest they may raise is attributed to political bias and the profession is acrimoniously flouted by "P. W. W.," who writes the parliamentary reports of the *Daily News and Leader*. Only last week he attributed the representatives' rejection to advantage taken of the recent Government defeat by a snap majority! The despair of chagrin could hardly hope for a more ingenious loophole, but despair seems to have run riot through the office of the journal in question about that period. The leading article of November 21st says that the fact that within less than two months the medical benefits must come into operation, a fact—according to the *Daily News and Leader*—gives the doctors a great strategic advantage. We have often insisted that the advantage was on Mr. Lloyd George's side, as he could spring upon the profession, without notice, some of those alternative plans paraded with so much jubilation by the same journal on former occasions. Then the "paucity of statistical information" is bewailed. "If the public could see before it in black and white," says the editor, "the financial position of the medical profession before and after the Act, and how much the profession will gain or lose by the Act, public opinion would intervene with decision on one side or other." That has the air of a sound proposition, and may be readily accepted. But what about a journal that admits the financial relations of a great profession are not understood, have never been authoritatively investigated, but are nevertheless to be at the mercy of a Government seeking to use the

services of that profession in a way that profoundly affects the conditions of their economic existence? We must be thankful to the *Daily News and Leader* for one thing, namely, their derision of the three years' provisional trial of the proposed terms, and with that view we are entirely in accord. Much is written between the lines of the following passage:—"Neither the Government," writes the editor, "nor anybody else is inspired by any feeling of hostility towards the profession; but the Government is the guardian of the nation's purse and the nation's health. It cannot satisfy a monetary demand which it feels to be unjust. It cannot rivet upon the State the tyranny of the second strongest professional organisation of the country. In the unhappy event of agreement proving impossible, the Government should elaborate in leisure—so far as it is the business of Government—the system which common sense commends. That would look like a war with the medical profession—an undignified conflict for the State—and there would not be sufficient guarantee that enough of the best medical talent would be at the disposal of the State." This is all admirable, and marks a chastened frame of mind when contrasted with the threats of alternative systems to be worked by dissident doctors. The perplexity of the *Daily News and Leader* may be traced in the final sentence, which runs:—"The guiding principles for the Government are to take ample time, and to take a long view, and to commit themselves to nothing which a far-seeing statesmanship would not sanction." That sentiment is contrary to the proposition laid down in the earlier part of the article, whereby much of Mr. Lloyd George's dilemma is attributed to the time spent in negotiations. The real fault lies in the want of due enquiry into medical economics before the measure was laid before Parliament. The element of time becomes more than ever perplexing to the journalistic partisan when he reflects that in two years a general election is due, and that a momentary triumph over a powerful profession, obtained by the aid of a party bludgeon, might be dearly paid for at the polls, were the inherent social weight of the medical profession to be put to an ultimate test in that undesirable fashion.

CURRENT TOPICS.

The Royal College of Surgeons, England, and the Insurance Act.

THERE was a notable and satisfactory change in the usual scene at the annual meeting of the fellows and members of the Royal College of Surgeons, England, held on the 21st inst. In place of the recurring resolution, directed against an unresponsive council for refusing the representation of members on that body, the meeting was mainly concerned with the attitude of the College towards the National Insurance Act. It is, of course, desirable that a strong corporation such as that concerned should do its best to advance the interests of the medical profession by discussing matters of definite medico-political importance. At the same

time it is not easy to see how their counsels are rendered clearer or stronger by the exclusion of members of the College. The present condition of affairs which prevents members from having a voice in their own government is a survival of class privilege that is grotesque in principle and mediæval in its injustice. It is to be hoped, therefore, that the fact of its lessened prominence at the meeting of last week marks no loss of zeal on the side of the reformers, but rather the rival attraction of certain intervening issues. Fellows and members would doubtless be well advised in the future to avail themselves of the annual opportunity afforded them by the council to bring forward for discussion the constitution of the College as well as medico-political questions in which the profession was closely involved. By this means pressure might be brought to bear upon the Government of the day in a manner which might prove fruitful. The resolution passed at the last meeting, endorsing the policy pursued by the council, was, so far as it went, satisfactory. But the resolution might, in our opinion, have gone further. The request should also have been made to the council to forward a copy of the resolution to the government official responsible for the introduction of the Insurance Act. This, had it been done, would have added to the value of the proceedings—and strengthened the position of the council in their dealings with the Government.

The Properties of *Catha Edulis*.

ONE of the distinguishing traits of national character, for the existence of which there would appear to be little reason save that of tradition, is the use of some stimulating beverage or drug. Whether it be tea, alcohol, bang, or hashish, custom has enacted that the nervous system of the different tribes of the human race shall be periodically soothed and excited by one or other of these agents. The subject of stimulant-narcotics was dealt with last week by Professor Ralph Stockman, M.D., F.R.S.E., Professor of Materia Medica and Therapeutics in the University of Glasgow, in the opening address delivered before the Pharmaceutical Society of Great Britain in Edinburgh. He referred more particularly to the *Catha edulis*, a small shrub growing wild in Abyssinia and the neighbouring mountainous districts of East Africa. The use of an infusion of the leaves is said to be older than that of coffee, the taste being sweet and astringent, somewhat resembling liquorice in flavour. The beverage produces a sense of refreshment, wellbeing, and wakefulness, while fatigue or hunger are warded off or lessened. It is also said that those accustomed to its use have a feeling of weakness and uselessness if they are deprived of it. Previous attempts to separate the active principles of the leaves had been unsuccessful, but Professor Stockman has succeeded in separating three alkaloids in a state of purity to which he gave the names cathine, cathidine, and cathinine. He has also found in the leaves sugar, tannin, caoutchouc, wax, and a yellowish essential oil having a very pleasant odour and flavour. The first alkaloid has an action something like a combination of morphine and caffeine, the active principles of opium and tea. Cathinine has not the same drowsy or depressing effect on the brain, but acts more as a stimulant to the spinal cord. Cathidine acts as a muscle poison and a slight stimulant to the nervous system. Broadly speaking, the action of the leaves is essentially comparable to that of other vegetable products which are used by mankind as stimulant-

narcotics. A full account of the actions of these alkaloids will, we understand, be published later.

Nervousness and its Cure.

OUR contemporary, *Musical News*, has recently offered some practical advice to performers and would-be performers upon the all-important subject of "nerves." Stage-fright is a common malady which affects not only actors and musicians, but also many other individuals who suffer considerable mental torture every time they appear in public from an exaggerated self-consciousness, leading to a morbid idea of failure. In the majority of cases, this pitiable state yields to one of greater confidence, or even of comparative ease, as soon as the performance has begun. Many eminent performers and public speakers have confessed to a feeling of extreme nervousness and dread immediately before their turn comes, but they obtain complete control over themselves directly they begin to play or speak. With some, however, the habit of self-confidence seems unable to be acquired, either from lack of mental training or from some inherent weakness of the nervous system, so that the talent of many really gifted persons never gets the chance to shine in public. To such, the *Musical News*, while appreciating the value, in certain cases, of hypnotism and suggestion, offers the gospel of auto-suggestion, diligently and daily practised, to the "complete exclusion of all the negative thought-poison of doubt, fear, or distrust." While agreeing in the main with the psychological teaching of the article in question, we should hardly consider it applicable to all cases of "nerves," so-called, some of which might, conceivably, be due to organic disease.

The Pollution of Rivers by Sewage.

THE eighth Report of the Royal Commission on Sewage Disposal was issued last week, dealing more especially with the important problem of the standards of purity to be applied to sewage and to sewage effluents discharging into streams and rivers, and the tests which should be applied to them. The Commissioners are of the opinion that the River Pollution Prevention Act of 1876 should be altered in such a manner as to allow local circumstances to be taken into account, and they conclude that the most trustworthy chemical index of recent sewage pollution of a river is afforded by the figure indicating the amount of ammonia present. But this constituent does not indicate the character of the pollution, for the determination of which another test is required, and the amount of the dissolved oxygen taken up in five days has been found by the Commissioners to furnish the most trustworthy chemical index of the actual state of a stream. They recommend that this amount should be adopted as a standard. With regard to the quantity of river water available for diluting a contaminating discharge, the Commissioners regard it as by far the most important of the various local conditions which should be taken into account in considering the question of standards, and they recommend the adoption of one general standard which, they state, can be attained by the complete systems of treatment that are available for sewage purification, and of special standards higher or lower than the general one, to meet exceptional cases. An effluent to comply with the general standard must not contain more than "three parts of suspended matters per 100,000, and with its suspended matter included must not take up more than two parts per 100,000 of dissolved

oxygen in five days at 65° F. (18° C.); this general standard to be prescribed by statute or by the order of the central authority, and to be subject to modification by the central authority after an interval of not less than ten years.

The Egregious Expert.

WHEN a man definitely decides to become a rigid specialist, he thinks that he is marching in the footsteps of natural advance. He compares himself with a cell, and finds that the more specialised the cells the more advanced the organism. As his work, experience and views become more and more narrow, the greater his self-appreciation is liable to be. He forgets one thing. No cell, nor group of cells, acts independently. They are all connected with others in the *corpus vile*. The man who lives and moves, and has his being only amongst experts of his own type, is merely an example of frenzied isolation. He thinks that nothing succeeds like excess; and nowadays he is succeeding. His day will not last, and even now it shows signs of waning—a truer reading of the proverb is that nothing recedes like success. Of course, no man can study medicine in its entirety—surgeons, physicians, eye-men, gynæcologists and so forth we must have. But the man who goes to Vienna for three months, and thence to Harley Street, and from that time forward confines his attention to bladders to the total exclusion of hearts, kidneys and other distant structures, is unnecessary. Let a man do some years' general practice, and unless his tastes are non-existent or unnaturally catholic, he will specialise automatically. To-day the specialist is largely a bearer of other men's responsibility or a scapegoat. His opinions should be treated gravely as such, and not as absolute, proven facts. He makes an excellent servant, but is a bad master.

Human Hair.

FOR some curious reason the medical profession has not devoted much attention to the study of cosmetics, but an interest in human crinology is really a practical one, and not derogatory to the dignity of a physician. The loss of body hair marked a distinct stage in the advance of primitive man, and is a direct factor in the universality of his distribution. He is cooler in hot climates and can clothe himself according to the circumstances of his latitude. The Chinese and Japanese are the least hairy races, and their climates show the greatest and most rapid changes of temperature to be found. That facial hair is a protection is well known to our soldiers and pioneers of civilisation in the wilder parts of the earth. Women did not need it and so it disappeared, and now its persistence in man is merely a sign that women like it—a secondary sexual characteristic. Provided we keep our beards clean, to beard or not to beard may be left to our own taste or the delicacy of our larynx. As a matter of fact, it is not improbable that the approval of the opposite sex has still some say in bringing down our hairs in sorrow to the shave.

The Colouring Matter of Flour.

AN interesting report (Food Reports, No. 19) has just been submitted to the Local Government Board by Dr. G. W. Monier-Williams on the nature of the colouring matter of flour and its relation to processes of natural and artificial bleaching. The amount of pigment in flour is present only in a very small quantity, but it is shown that it is either carotene, the colouring matter of the carrot, or a substance or mixture of substances so closely allied

to carotene that the absorption spectra are practically identical. The colour of carotene may be discharged either by the oxygen of the air or by nitrogen peroxide, the two processes being quite distinct and resulting in the formation of different substances. It is concluded that the natural ageing of flour is due to a bleaching process by absorption of oxygen, whereas in the artificial bleaching by nitrogen peroxide certain substances, present in exceedingly minute amounts, are produced which are not formed during the natural ageing of flour. Therefore, artificially bleached flour is not quite the same thing as flour that has been naturally aged. Further experiments were undertaken to ascertain the amount of nitrate reacting substance present in flour and the degree to which this tends to increase on storage. Unbleached samples showed on the average an increase of nitrate from 0.4 to 1.2 parts NaNO_3 per million, while the bleached samples which already contained 1.6 parts per million showed no increase at all, except in one instance.

Eurhythmics.

THE cultivation of graceful movements and gestures has not always been the main object of teachers of gymnastics, who, not unnaturally, believe that symmetry of form and uprightness of stature are more to be desired than mere beauty of gesture. According to the newest apostle of Greek ideals, M. Jacques Dalcroze, true grace of form and movement depends upon equilibrium and rhythm. The doctrine of co-ordination of brain and muscle, working in rhythmical harmony, has been studied by this professor of musical gymnastics for the last five years at his college at Hellerau, a garden city near Dresden. At an exhibition of his pupils' work, held at the Caxton Hall last week, it was quite obvious that his system was something more than a mere slavish imitation of the Hellenic gestures and attitudes in which individuality is, for the most part, completely ignored. The new method of eurhythmics seeks to educate the muscular system according to the laws of rhythm which, in conjunction with ear training, appear to lead to better results than when automatic movements are less studied. M. Dalcroze states that the English are naturally a rhythmical nation, and that English children respond most readily to his system. As long as such a method is not openly "boomed" as a new cure for nervous and other maladies, one can imagine nothing but good from its adoption.

PERSONAL.

H.M. THE KING in Council has nominated Dr. John Christie McVail, M.D., to be, for a period of five years from October 28th, a member of the General Council of Medical Education and Registration of the United Kingdom, for Scotland, and Dr. James Little, M.D., to be, for a further period of five years from November 26th, a member for Ireland.

THE LORD LIEUTENANT OF IRELAND has appointed Sir Stewart Woodhouse, M.D., to be a Governor of the House of Industry Hospitals, Dublin.

MR. F. A. SOUTHAM, F.R.C.S., has been elected a member of the Court of the Manchester University.

MR. T. O. GRAHAM, F.R.C.S.I., has been appointed Assistant in Throat Surgery to the Royal City of Dublin Hospital.

DR. HARRY SAMUEL has been appointed Clinical Assistant in the Skin Department of University College Hospital.

MR. BERTRAM ARTHUR LLOYD, M.B., B.S.Lond., F.R.C.S., has been appointed Resident Medical Officer at Charing Cross Hospital.

DR. GEORGE JEFFREY, M.D.Glasg., F.R.C.P.Edin., has been appointed Physician-Superintendent to the Bootham Park Private Mental Hospital, York.

DR. W. M. ETTLES will give a lantern demonstration on diseases of the eye at the meeting of the Hunterian Society at the London Institution, Finsbury Circus, at 9 p.m. to-night.

MR. STANLEY BOYD, M.S., F.R.C.S., will preside at the annual dinner of the Royal Free Hospital and London School of Medicine for Women, at the Trocadero Restaurant, Piccadilly, on December 11th.

MR. E. GERALD GAUNTLETT, M.B., B.S.Lond., F.R.C.S., has been appointed Assistant Surgeon to the Paddington Green Children's Hospital and Senior Surgical Registrar and Tutor at King's College Hospital.

PROFESSOR H. E. ANNETT, whose research work for the Liverpool School of Tropical Medicine is known, has opened at Runcorn, his native place, a dispensary for the free treatment of poor consumptives by means of tuberculin.

MR. C. MANSELL MOULLIN, M.D., F.R.C.S., will deliver the Bradshaw Lecture in the Theatre of the Royal College of Surgeons of England, on Thursday, December 6th, at 5 p.m., on "The Biology of Tumours."

CAPT. H. L. HOWELL, R.A.M.C., has been selected for appointment as a Specialist in the Prevention of Disease and placed in charge of the Brigade Headquarters Bacteriological Research Laboratory at Ahmednagar, Bombay Presidency.

THE degree of D.Sc. in Bio-Chemistry has been conferred on Dr. Casimir Funk, Ph.D., an internal student of the Lister Institute of Preventive Medicine, for a thesis entitled, "A Chemical Investigation into the Cause of Beri-Beri," and other papers.

MR. AUSTEN CHAMBERLAIN has received £48,000 towards the £100,000 which he is raising for the London School of Tropical Medicine. He has been elected a Vice-President of the Corporation of the Seamen's Hospital, to which the school is attached.

MR. P. W. MAXWELL, F.R.C.S.I., has been appointed Surgeon to the Royal Victoria Eye and Ear Hospital, Dublin, in room of the late Mr. Arthur H. Benson, and Mr. L. Werner, F.R.C.S.I., has been appointed Junior Surgeon in place of Mr. Maxwell.

MR. WILLIAM S. LANGWORTHY, M.R.C.S., L.R.C.P., of Yealmpton, Devon, was presented the other day with a silver spirit kettle, a walking-stick, and an illuminated address as a token of respect and esteem upon the occasion of his leaving the district after seventeen years of medical practice therein.

MR. EDWARD GEORGE BETTS, M.R.C.S., L.D.S., I.S.A., a former secretary and president of the Odontological Society, and a former hon. treasurer of the British Dental Association, who died on October 6th, left estate of the gross value of £43,495, of which the net personalty has been sworn at £41,306.

THE following are the six selected candidates for the vacant medical officership of health for the City of London: Dr. A. M. Fraser, of Portsmouth; Dr. A. Greenwood, of Blackburn; Dr. W. J. Howarth, of the County of Kent; Dr. R. A. Lyster, of the County of Hants; Dr. J. F. Taylor, of Leyton; and Dr. W. M. Willoughby, senior assistant to the medical officer of the Port of London.

A CLINICAL LECTURE

ON

FEVER : ITS CAUSES AND TREATMENT.

By E. C. HORT, F.R.C.P.Ed.

Delivered at the Polyclinic, Chenies Street, W.C., on Thursday, November 7th, 1912.

IN discussing fever it is well to define exactly in what sense we use the word. This has become necessary owing to the modern tendency to deprive the terms fever and pyrexia of the sense they used to hold, and to create thereby quite unnecessary confusion.

By fever in the early days of the clinical thermometer was simply meant a rise of internal body temperature above the normal range, because such rise was then, as it is now, often the most noticeable feature of the feverish state.

This use of the word has the sanction of custom and convenience, and, as a rule, leads to no misunderstanding.

The word fever, however, is also often used as an abbreviation for the state of fever, in which, although a rise of internal temperature above the normal range is an essential element, there are other factors to be considered. Amongst such factors are the familiar disturbances of the functions of the heart, lungs, skin and other organs that usually accompany any marked degree of fever.

This use of the word is also quite legitimate, and any case of doubt as to which of these two uses is implied can generally be settled by reference to the context.

The third use of the word fever is the generic one, by which we denote, with suitable prefix, different groups of infective diseases. We have, for example, the eruptive fevers, the bacterial fevers, the protozoal fevers, and so forth.

As is well known, it sometimes happens that an infective disease may run its course, even in fatal cases, without any rise of internal temperature above the normal range, although other indications of profound toxæmia may be present. For example, in some pneumococcal infections if the dose of poison be relatively large, or if resistance thereto be unusually feeble, the toxic agents associated with the disease may cause a marked fall of temperature below the normal range, or may even not affect it. In order to draw attention to this fact, some of our best writers on fever speak of a fever—meaning an infectious disease—in which there is no fever—meaning no rise of temperature. And in order to escape from the paradox that in a fever there may be no fever, they insist that the word must not be used to denote rise of temperature alone, and they, therefore, substitute the word pyrexia. We hear, in consequence of fevers that may be pyrexial or non-pyrexial. Apart from the obvious fact that without rise of internal temperature there can be no fever or state of fever, these writers forget that pyrexia means the state of fever, and is not an equivalent for fever in the sense of rise of temperature alone.

This is the confusion that has sprung up in recent text-books. It can, however, be readily avoided if we remember that pyrexia and the state of fever are interchangeable terms, both implying that though a rise of internal temperature above the normal range is the essential factor in the sum total of the feverish state, other factors must be considered. If we elect in any given case to apply the word fever to rise of temperature alone, it is always possible, and, in fact, customary, to state in such case the presence or absence of any or all of its well-known accompaniments.

We now come to the causes of fever.

By far the commonest cause of continued fever in man is the presence of pathogenic organisms. In all cases of bacterial or protozoan disease we have to consider therefore—

A. The primary cause of the fever, the nature and

variety, that is, of the causal organism. This, of course, is mainly a bacteriological problem.

B. The nature and source of the actual body or bodies absorption of which is the essential cause of the fever. This is largely a chemico-physical problem which must be kept quite distinct from A.

C. The method of action of the actual fever producing substance on the mechanism of adjustment of heat production and loss, be such adjustment under nervous control, as we believe, or not. This is a physiological problem, and is the end point, so to speak, of the action of A followed by absorption of B, and is so far quite distinct from the problems presented by either A or B.

We are here concerned only with A and B and shall neglect C.

A. It is, as we have seen, very generally admitted that the primary cause of fever, as we meet it in practice, is in the majority of cases the presence of bacteria or protozoa in a pathogenic state. Slight degrees of fever of a fugitive nature may, of course, occur in perfectly healthy subjects as the result of exercise, baths and so forth, as was fully demonstrated by Davy in his Royal Society papers in 1863. Incidentally it may be said that study of the slighter degrees of fever is unsatisfactory if mouth or surface temperatures be taken. For this purpose, and in all experimental work, rectal observations are alone permissible if it is desired to obtain records of internal temperature. Other direct disturbances of nervous control of the balance between heat production and loss leading to fugitive fever are seen in some of the convulsions of children who are notoriously unstable in all their powers of adjustment. Mere muscular activity is a negligible cause of fever as hyperaction of all the muscles of the body may in animals be associated with profound fall of temperature in certain toxæmic conditions. In the fever associated with convulsions in children, and in other similar forms of fever, it may, perhaps, be unnecessary to invoke the presence of causal organisms. There is, however, a fairly large group of cases of fever in which, although it is at present impossible directly to implicate the action of micro-organisms, it is equally impossible to exclude the likelihood of their action. This is particularly the case since the work of Conradi and others on the ubiquity of organisms leading a saprophytic existence in the body organs. So long as no injury to these organs takes place fever may be absent because these organisms are not able to assume a pathogenic rôle. Once injury has occurred, however, the saprophytic may become pathogenic, and fever may ensue. In this class it is possible that many varieties of obscure fever will eventually range themselves. Such, perhaps, is the fever of malignant disease, which as a rule is not marked until autolytic changes in the growth are in full swing, apart, of course, from ulcerative lesions involving free surfaces. The same may also be true of many of the profound anæmias not primarily due to parasitic invasion, of hæmatomata, of simple fractures, of visceral hæmorrhage, and of atrophic and autolytic diseases of the liver. In all of these it is possible that the presence of dead cells afford a pabulum for micro-organisms and opportunities of conversion of saprophytic life into pathogenic activity. Here there is no necessity for invoking fresh infection from without in the ordinary sense of the word. In this category, also, probably comes the fever that we know as duct fever. Injury to bile ducts, by the partial or complete passage of calculi, injury to ureters

by renal calculi or minute concretions, slight abrasions of urethra or ureter by perfectly sterile catheters, may afford, and I believe does afford, opportunities for conversion of organisms leading a saprophytic existence in the ureter, bile duct, or other types of ducts, into organisms capable of producing marked or even serious fever. If this be true, it may be well to remember that the passage of even absolutely sterile instruments into ducts for purposes of diagnosis should not be undertaken unless absolutely necessary. In cases where bacterial disease already exists, for example in the kidney, it often happens that severe fever is set up by diagnostic passage of instruments. In such cases the surgeon is often wrongly accused of introducing imperfectly sterilised instruments, whereas the real explanation may be that he has inflicted some slight abrasion which he could not possibly avoid.

Next come the fevers associated with injury to the nervous system. In many of these the fever has been ascribed to injury of hypothetical heat centres. If the published records of these cases are carefully examined it is surprising in how few bacterial infection from wounds can be certainly excluded, quite apart from the possibility of conversion of saprophytic organisms into active fever producers in the absence of external wounds. In most of the experimental operations undertaken for the production of so-called nervous fever there is a surprising absence of control observations. In many of the operations the incision wounds were repeatedly sponged with dilute solutions of carbolic in water that we now know may have been itself strongly pyrogenetic. The injection of water or saline containing small quantities of pyrogen direct into the brain of animals produces high fever. These remarks must not be taken to mean that a true, nervous fever from injury of heat centres does not exist, only that the evidence so far produced is not very good. Finally, there are the so-called nervous fevers associated with the presence of cerebral tumours. And even in these it appears that fever is far commoner in the case of infective granulomata of the brain than in the case of non-specific tumours.

Next come the transient attacks of fever associated with the injection or ingestion of various substances which till recently were quoted far and wide as examples of fever that had no connection with the presence of micro-organisms. I refer especially to saline fever, transfusion fever, both as regards transfusion of blood and of saline, carbohydrate fever, anaphylactic fever, anaesthesia fever, salvarsan fever and protein fever. In each and all of these the particular substance injected has been credited with the possession of specific fever-producing properties. Recently, however, I have shown with my laboratory colleague Dr. Penfold, that all the experiments hitherto relied on in support of the existence of these different entities of fever must be rejected. We found, in short, that we could reproduce none of these fevers if we used as our medium of injection pure water or saline. The mistake apparently arose from the tendency that all water or saline has of picking up contamination with a heat stable filter passing substance that readily produces fever. The source and chemical nature of this elusive body are still quite unknown, though an essential factor in its production appears to be infection of the water or saline from the air. We have shown, however, that the presence of this contamination in water or saline holds no constant relation to the number of organisms capable of demonstration in these liquids before sterilisation. This form of fever in practice is seldom serious and is always fugitive. No treatment for it is required, as it can always be prevented by using water, in the preparation of saline, that has either been distilled immediately before use, or that has been stored in hermetically sealed flasks. In many operating theatres ordinary boiled tap water is used for the manufacture of saline. The amount of this fever-producing substance in London tap water is slight, but if large quantities are used, as in the treatment of surgical shock or collapse, a definite degree of fever may be produced, in spite of the fact that the water before boiling gave no organisms capable of cultivation. The use of tap water, therefore, is not to be recommended.

So far we have dealt only with the somewhat rarer forms of fever met with in practice, and have not touched on the fevers that are unquestionably due to the presence of bacteria or protozoa. For the most part the fevers we have mentioned are fugitive in nature, and the fever is, in many cases, not a serious affair. In most of them, however, it is almost impossible to exclude the action of micro-organisms either from direct introduction from without or by conversion from a non-pathogenic state into a pathogenic as the result of cell injury or death.

There remains the large group of diseases in which fever occurs as the result of recognised causal organisms or protozoa, including those in which the *materies morbi* is still unknown. Their name, of course, is legion, the exanthemata, coli infections, influenza, malaria, trypanosomiasis, and all the rest of them. In all of these the appropriate methods of discovering, where known, the causal organisms are sufficiently familiar. But before leaving this subject it may be well to insist that when all the ordinary tests have been carried out, it is still necessary to remember, in case of negative results, that in any serious case of continued fever in man bacteria or protozoa must still be looked for. In other words, it is necessary before falling back on such diagnoses as nervous fever, hysterical fever, carbohydrate fever and the like, to examine bacteriologically all the fluids of the body. And in certain cases this should be done, not once but many times. It has frequently happened to me to see cases in which a single bacteriological examination of the urine, for example, has been carried out with negative results. In such cases repeated examination has not seldom furnished the missing clue, especially where *B. coli* has been the offender. Isolated examinations, if the result is negative, are useless, because the appearance of organisms in the urine is often a question only of discharge. Not long ago I saw a case with intermittent attacks of high fever, which subsequently proved to have been caused by infection from a kidney stuffed with abscesses. In this case repeated examination of the urine was necessary before organisms could be cultivated with sufficient readiness to justify exploration. I have recently seen cases in which recurrent attacks of phlebitis associated with high fever proved eventually to be due to coli infection of a kidney containing calculi. In one such case there was no history of renal colic, and the urine was free from coli for months, and yet the attacks of infective phlebitis recurred. The treatment of such cases I will return to later.

Before passing on to the essential cause of fever in diseases due to the presence of micro-organisms, it is necessary to point out that, though clinically we have done our duty if we discover the causal organism in any given case, we are still quite in the dark as to how the fever arises. If, for example, we meet a case of pneumococcal infection, we know that if we can get rid of the pneumococcus, or put it out of action, we may be able to get rid of the fever. And, from the clinical standpoint, this is no doubt sufficient. From the pathological standpoint, however, it is not sufficient. We have at present not the remotest idea in what way the pneumococcus produces fever, nor do we know in what way any of the bacteria or protozoa cause fever.

And this brings me to B, the chemico-physical causes of fever, for want of a better name.

B. What is the essential cause of fever in diseases due to the presence of micro-organisms? This, of course, is more a pathological problem than a clinical, and I will not, therefore, do more than refer to a few points presented by the problem of fever as a whole. Stated briefly, the pivot of the problem is this. Granting, as we must, that without the presence of the *B. typhosus*, for example, typhoid infection cannot take place, what is the fever due to? Is it due to absorption of fever-producing substances derived from the dead bacillus typhosus, or is it due to absorption of fever-producing bodies set free from the cells of the infected subject as a result of the action of the living bacillus on those cells? Or, thirdly, is it due to the direct action of the living bacillus on nerve cells? Once we can answer these questions we are a long way toward

answering some of the clinical problems presented by fever. At present, we can only say we do not know. Until quite recently it has been universally assumed that the pyrogen, or substance, that is, which causes fever by upsetting the nervous mechanism of adjustment between heat production and loss, is derived from the dead bodies of the invading micro-organism. Evidence in support of this belief was supposed to be afforded by experimental observations in man and on animals in which fever undoubtedly followed the injection of certain organisms after their destruction by heat or chloroform. These experiments had apparently never been called in question till this summer. Further, it was assumed that because injection of certain organisms after their destruction was followed by fever, this was necessarily true of all organisms. During this summer, however, I published the results of several thousand experiments carried out in my laboratory in the Lister Institute by myself and Dr. Penfold, and showed that the evidence hitherto relied on to prove the cause of fever in infective disease no longer exists. We showed, in fact, that if precaution be taken to suspend certain varieties of killed micro-organisms in pure saline or water before injection no fever whatever resulted. The fallacy I have already referred to that is due to the use of contaminated water or saline was, in short, the cause, in some instances, of the belief in pyrogenetic properties of certain varieties of bacteria or cocci. This was, for example, the case in certain strains of staphylococcus aureus, B. diphtheriæ, B. anthracis, and others. We also showed that dead organisms, such as B. typhosus and B. coli, which unquestionably do produce fever immediately after injection, even when suspended in pure water, apparently only do so because they have picked up from the laboratory media on which they have undergone cultivation a fever-producing substance derived from such media. In other words, it seems that the pyrogenetic properties of dead organisms is merely due to contamination derived from the media employed for growth. The work is not yet complete, but we believe we have in these experiments obtained good evidence that the fever of infective diseases is not due to absorption of bacterial pyrogen derived from the dead organisms, but is due to the action of the living organisms on the tissues of the host. A full account of some of these experiments is to be found in the current number of the *Journal of Hygiene*.

The immediate practical importance of these observations on the practice of injecting dead bacterial vaccines is obvious. Many vaccines, for example, of B. typhosus, B. coli, and others, whether employed for prophylactic or therapeutic purposes, are, of course, known to produce in a short time marked fever with all its unpleasant accompaniments. As we showed in July last at a meeting of the Pathological Society in Newcastle it is quite possible so to treat these vaccines that they are deprived of this power of producing fever. Once it can be definitely established, and this we are now working at, that contamination of these vaccines by this fever-producing substance derived from the laboratory media, is of no advantage to the subject receiving the injection, it will become necessary to eliminate from all vaccines this undesirable effect. On the other hand, it may prove to be the case that much of the benefit derived from the use of dead vaccines is in reality due to injection of this contamination. In this case it becomes very necessary to recast our ideas as to the method of action of dead vaccines in the treatment of serious infective conditions, and to determine the real value, from the immunising standpoint, of purified vaccines freed from this contamination. There are other interesting points raised by these experiments which for the moment appear to be of more theoretical than clinical value, and we will, therefore, pass on to the treatment of fever.

The treatment of fever is of two kinds—palliative and specific.

The palliative treatment of fever is to a large extent merely the treatment of the symptoms of the feverish state. Apart from diet, rest, baths, adequate air supply, and so forth, reliance in the past has been chiefly placed on drugs—mainly of coal tar origin. To-day we realise that the use of phenacetin, antipyrin,

aspirin, salicin, and similar preparations is of very limited value in the treatment of fever. At present we do not even know whether fever is a conservative process or not. Until we do possess this knowledge it is an open question whether the use of these drugs is justifiable, except as a temporary expedient to relieve distress. Their continued use may, on the other hand, do considerable harm, even apart from their depressant effects. In the palliative treatment of hyperpyrexia there are other better methods to employ, such as baths and sponging. In the treatment, however, of hyperpyrexia I have sometimes obtained great benefit by the rectal injection of large quantities of hot saline. The immediate effect is to cause a still higher degree of fever. This, however, in cases that have not been left too long, is quickly followed by a fall of temperature of several degrees, the procedure, in fact, producing a crisis. In a case I saw not long ago of hyperpyrexia in measles, the effect was most gratifying.

The specific treatment of fever, on the other hand, resolves itself into a question of the specific treatment of the condition that gives rise to fever. Since continued fever in man is in the majority of cases due to infection, specific treatment of fever becomes a question mainly of its prevention. In other words, we cannot at present treat fever, but can only hope to prevent its appearance or continuance by successful prevention or treatment of the infection on which it depends. This we do in one of two ways. We either attempt to remove, or, failing this, to destroy or neutralise the action of the causal organisms, or we attempt to effect relative or absolute immunity to their action.

The chief methods in use to-day, other than surgical, for the specific treatment of fever are those offered by chemotherapy, serum therapy, and vaccine therapy.

The successes obtained in specific chemotherapy by quinine, salvarsan, and antimony in the treatment of malaria, syphilis, and the trypanosomiasis, suggest that there is a great future for this branch of specific treatment. How far the colloidal chemists will be able to provide us with colloidal metals in a relatively non-toxic state, for example, we ought soon to know, if we may judge from the large number of workers engaged on this subject.

A second specific method of preventing or treating fever still on its trial is vaccine therapy. Of this there are two forms fundamentally different. In this country the injection of emulsions of dead organisms for protective and therapeutic purposes—as regards fever—is having an extensive trial. In the treatment of continued fever there is a widespread belief in their efficacy for this purpose which cannot be set aside. Personally, I have not yet come across a single case of serious continued fever where the treatment can be credited with success. I have, however, seen many cases where, after extensive trial, its failure was admitted. This, however, may be a very exceptional experience. Quite apart, however, from any therapeutic value that dead vaccines may have in continued fever, there is no gainsaying the fact that toxic symptoms, not necessarily serious, do sometimes follow their injection. And the shortness of the time in these cases between injection and increase of the fever, leaves no doubt as to the relation between cause and effect. As we have already seen, as soon as we are sure that the injection of adventitious pyrogen derived from the medium of growth is of no value, it will become very necessary to use only vaccines that have been freed from this contamination. If, on the other hand, it prove to be an advantage to use contaminated vaccines, it then becomes necessary to determine what specific value can be properly ascribed to vaccines that are not thus contaminated, so far, that is, as the treatment or prevention of fever is concerned.

The second form of vaccine therapy consists in the injection of living organisms, and sometimes of dead, that have been sensitised by incubation with immune serums. The method was originally introduced, on an extensive scale, by Sclavo for the prevention of anthrax. It has since then been taken up by Metchnikoff and Besredka, and modified by them and other workers. So far it has been mainly used, though not entirely, for prophylactic purposes. The great

point claimed for the method appears to be that living vaccines can be used with impunity, and with better immunising results, provided certain precautions are taken, if the organisms before injection are sensitised with immune serums. It is claimed that by this method the vaccines are to a large extent detoxicated, both as regards local and general reactions, though it does not appear that the pyrogen contamination from the media of growth is necessarily removed. It is much too early for general use of these vaccines, but it is possible that the method may entirely replace the somewhat haphazard method of dead vaccine therapy at present under trial in this country.

In the meanwhile the method opens up a wide field of development of the somewhat neglected science of immune serum therapy. Hitherto we have believed that the scope of immune serums was restricted to the provision of passively immunising agents. For instance, the unrivalled success of anti-diphtheritic serum is generally believed to be merely a question of passive immunisation. If, however, it be true that living vaccine becomes a better agent in the production of active immunity if it be first sensitised with immune serum, it is possible that in some diseases an anti-bacterial serum may be of greater value than an antitoxic, though in a different sense to that usually held. It is, in fact, legitimate to suggest, though so far as I know the suggestion is a novel one, that the real value of good immune serums (apart from diphtheria) may lie, not in their antitoxic or bactericidal properties so much as in their ability to sensitise *in vivo* the potential vaccines the infected body already holds. In other words, immune serum therapy may prove to have great values hitherto undreamt of. In such event the immediate practical problem will be the determination of the kind of antigen to use in the preparation of such serums. The whole question is one of fascinating interest, and there for the present we must leave it.

NOTE.—A *Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Herbert French, M.A., M.D. Oxon., F.R.C.P.Lond., Assistant Physician to Guy's Hospital, &c. Subject: "Some Therapeutic Points."*

ORIGINAL PAPERS.

RADIUM IN GYNÆCOLOGICAL CONDITIONS.

By DR. W. H. B. AIKINS,

Consulting Physician, Toronto General Hospital, Toronto Hospital for Incurables, King Edward Sanatorium, &c.,

IN COLLABORATION WITH

F. C. HARRISON, B.A., M.B.,

Physician, Toronto Hospital for Incurables; Assistant in Pharmacology, University of Toronto, &c.

RADIUM has recently been used with varying success in certain gynæcological conditions, and in some of these the results indicate the possibility that it may in future prove of still greater value.

Among the conditions which are reported to have been favourably influenced by the application of radium are included cancer of the uterus, cancer of the vagina, fibroma of the uterus, metritis, chronic urethritis, inflammation of Bartholin's glands, and pruritus of the vulva. Jacobs (1) also recommends radium treatment for membranous dysmenorrhœa, chronic pelvic cellulitis, chronic salpingitis, and epithelioma of the vulva, but Finzi's (2) experience indicates that in the latter condition its beneficial results are problematical, and he is of opinion that in some of the cases which have come under his observation the growth of the neoplasm, instead of being favourably influenced, has even been accelerated by radiation.

The histological changes, which have been demonstrated in malignant growths after intense radiation, are in the first place invasion of the neoplasm by the leucocytes, with accentuation of the normal cell changes. This is followed by disappearance of some of the cancer cells, which are replaced by fibrous

stroma, and finally by fibrous tissue. There is also cell degeneration, especially in the superficial portion of the growth, and proliferation of the endothelium of the blood-vessels. Wickham and Degrais (3) are of opinion that these changes are of a curative nature, and that there is invariably a definite proportion between the intensity of the radiation and the number of cells destroyed. Histological investigations have demonstrated that these degenerative and destructive changes extend to a depth of nine centimetres from the surface.

An important consideration in regard to radium therapy, as applied to malignant disease, is the fact that both the Röntgen and radium rays have been shown to exert an elective influence on cancerous growths, the superiority of radium in this respect being due to its action on the deeper tissues by means of the gamma rays. This action results in degeneration and destruction of the neoplastic cells only, the normal cells remaining unaffected, and it varies enormously in different varieties of tumours. It is accentuated by increased intensity of radiation, and the use of larger quantities of radium, so that a growth which has proved refractory to small doses for a prolonged period may possibly yield within a comparatively short time to larger doses. The action of the penetrating radium rays is considerably more selective than that of the Röntgen rays, so that they are much more likely to influence deep-seated growths. In this connection it should be borne in mind that, in addition to this selective action varying in different varieties of neoplasm, it may also vary to a certain extent in the same type of growth in different individuals, so that they will not require applications of the same degree of intensity.

Cancer of the Uterus.—The first reference in literature to the employment of radium in the treatment of cancer of the uterus is in a paper published in 1905 by Dr. Abbé, of New York, who has since done a considerable amount of work in this connection.

With the improved instrumental technique which we now have at our command, by means of which radium tubes can be introduced directly into the body of the uterus, a large and suitable field for utilising the therapeutic qualities of radium has been opened up.

The apparatus which has been recently designed is very adaptable to this region, and as it can be fixed and kept in position for many hours it has the great advantage of allowing of long-continued application of the rays. These technical improvements, and the fact that clinical experience has now shown us the physical qualities of the rays and the quantities of radium which are necessary if we desire to obtain certain definite results, render the treatment of the greatest value in uterine conditions, and indicate the possibility of its taking a still more important position in the future. The small size and convenient shape of the apparatus allows of complete saturation of a uterine cancer with the rays, which are therefore superior to the X-rays in this connection.

The experience of Nammacher, Rubens-DuVal, Finzi, Wickham and others shows that radium has already been of great service in disease of the uterus, and that it is a most useful adjunct to surgery in this region, as well as in other parts of the body. In inoperable cases it often facilitates surgery by reducing the thickness of the neoplastic tissues and diminishing the malignancy of the field of operation, and from a prophylactic point of view most satisfactory results have been obtained from post-operative radiation of cicatrices. Even if operation is not rendered possible, in the majority of cases of malignant disease of the uterus radium treatment is beneficial to a certain extent in relieving intolerable pain and diminishing discharge. In some cases the "cross fire" method, namely, a combination of internal and external applications, is of great service. Owing to the facility with which radium tubes can be introduced into the body of the uterus, uterine conditions are very suitable for treatment, and in addition to this the analgesic, hæmostatic and decongestive properties of the rays are adapted to meet the requirements in the treatment of malignant disease of this organ. It is advisable to

select apparatus by means of which applications of the greatest possible intensity can be given, in order to avoid the disadvantage of too long-continued applications.

J. H. McLeod (4) states that in his experience the destructive action of radium in relation to the cancer cells has not apparently been so marked in cancer of the uterus as in more superficial conditions, but he thinks that this peculiarity may very possibly be explained by the difficulty of access to uterine growths, of watching and controlling the radium applications, and also by the great rapidity of malignant proliferation.

In this connection we would report three inoperable cases where the use of radium has been of distinct benefit. The first of these cases was reported by us in January, 1911 (5), and the improvement has been continued.

Case 1. A patient, æt. 53, referred by Dr. Tuttle, of Tweed, Ontario, first noticed a bloody uterine discharge in January, 1910. She did not consult a physician until June. The cervix was cauterised, but serious hæmorrhage recurred, and in July she underwent an operation at the hands of a leading gynaecologist in Toronto, when the uterus was curetted, and the cervix amputated. This was all that was done, as, in the surgeon's opinion, the left ureter and bladder were involved, and hysterectomy would not be justified. A very grave prognosis was given.

On August 5th she consulted regarding radium treatment. The discharge, pain, and irritability of the bladder had continued. Dr. F. A. Cleland, Gynaecologist at St. Michael's Hospital, Toronto, was called in consultation, as it was felt that the treatment should be surgical, if possible.

The condition at that date, as reported by Dr. Cleland, was as follows: "On August 15th, in the vault of the vagina, and where the cervix had been removed, was a raw, bleeding, granular surface, about two inches in diameter, extending into the vaginal wall. The left side was more involved than the right, and in order to remove the growth completely, an extensive dissection would have been required, and probably the removal of the left ureter.

"The uterus was fixed on the left side, and examination by bi-manual method caused a good deal of pain. The body of the uterus was not enlarged.

"In view of the extensive operation which would have been necessary, and the uncertainty of complete removal, radium treatment was advised."

This patient has been under observation for over two years. Her general health has much improved, and she has increased in weight. At intervals, prolonged exposures to the radium rays, from tubes placed against the cervix, have been given. Local examination at present (September, 1912) would indicate that there has been no extension of the disease. The uterus is, if anything, more movable than at first, and there are no bladder nor bowel symptoms. The ulcerated area of the cervix has decreased, but not entirely, and now presents a small central ulcerated area, surrounded by firm fibrous tissue. There is no odour to the slight discharge.

Case 2. First came under observation on June 15th, 1911. The disease was considerably more advanced than the first case. She had been curetted as a palliative measure, but had had considerable bleeding since. Dr. Cleland was consulted as to the possibility of surgical treatment. He found the uterus fixed to the surrounding parts, and considerable extension on to the bladder. The cervix presented a large area of ulceration, which bled readily. Encouraged by the results obtained in Case 1, we decided to try radium. Almost from the first the bleeding stopped and the patient put on weight. She is able to be about, and enjoys a comfortable life. She has been continuously under observation since. There is an occasional slight bleeding, and some abdominal pain, no doubt caused by the adhesions to the surrounding organs. Dr. Cleland has also seen her from time to time, but has not advised further curettage or other operative measures, as the radium treatment seems to be holding the disease process well in check.

Case 3. Patient, 52 years of age, referred by Dr.

Brandon, of North Bay. Came under observation March 3rd, 1912. She suffered from a cancer of the cervix, and had been curetted some weeks before. She was having almost continuous hæmorrhages, was confined to bed, and the condition was regarded as so desperate that her husband was told by a surgeon in consultation that nothing could be done but wait for the end. When seen the condition was most assuredly a grave one. She was weak and exhausted from constant loss of blood. On examination the cervix was quite excavated, forming a crateriform ulcer, and the growth had extended on to the vaginal walls. Dr. F. A. Cleland, who was called in consultation, agreed as to the inoperable character of the case, and advised that radium treatment should be tried. She was given a very heavy exposure, much more than either of the previous cases. The bleeding soon ceased, and has only reappeared occasionally since. She put on weight, and was soon able to be about each day. The area of ulceration has steadily lessened, and all macroscopical evidence of cancerous growth in the vaginal walls has disappeared.

Chronic Urethritis.—Although the results of radium treatment in this condition have so far been very uncertain, it has been beneficial in several cases, and it is therefore justifiable to undertake it when the usual therapeutic measures have been tried without success.

Pruritis and Vulvar Vegetations.—Good results have been obtained from the use of radium in such cases, chiefly owing to its analgesic properties. Wickham reports the case of a woman aged 62, who suffered from vulvar and perineal pruritis of ten years' standing. After two series of applications the patient had long intervals of comparative comfort, and the pruritis gradually disappeared altogether.

Lupus of the Vulva.—Improvement has also been reported in cases of obstinate lupus of the vulva, and in chronic ulceration, presumably due to blenorragia.

Dr. Wickham strongly emphasises the imperative necessity of the association of radium treatment with surgery whenever possible, and that it should not be regarded as an independent form of treatment, but merely as an adjunct to surgery. Up to the present it has been chiefly employed in inoperable cases, but it has an extensive field of usefulness in the pre-malignant stage and in post-operative prophylactic treatment, and it has been found of great service to surgery in rendering operable tumours which are inoperable or practically inoperable.

A SKETCH OF THE DEVELOPMENT OF THERAPEUTIC IMMUNISATION (a)

By W. BOXWELL, M.D., F.R.C.P.I.,
Physician to the Meath Hospital, Dublin.

IMMUNITY to disease can come about in a variety of ways. Some are said to be naturally immune to many diseases to which others are prone, and live through many an epidemic, say of mumps or measles without ever becoming infected. Others become immune through having had the disease. One attack of small-pox usually makes a man immune for life.

Artificial immunity to a particular disease lasting for a variable time can be brought about by injecting the microbes of that disease in an enfeebled form into the blood of previously susceptible people or animals, the injection acting as a stimulus to the formation within the body of protective anti-bodies. This is called active immunity, while the blood serum of an animal so protected—such as a horse—may be injected into a

(a) An Inaugural Address to the Students of the Meath Hospital at the opening of the Session 1912-13.

human being, and confer upon him, as it were, a ready-made immunity. Here the horse serum, charged with protective anti-bodies, acts as an antidote, neutralising the microbial poisons exactly as an alkali will neutralise an acid. The immunity so established is called passive immunity.

It is obvious that the first and second forms of immunity are not available for practical purposes. The development and extension of the third and fourth have acted like a lode in attracting the best brains in the world of pathology since Pasteur.

How it was that Pasteur, a pure chemist, came to be the first and greatest bacteriologist is another story. Let those who do not know go and read about him. It is sufficient here to remind you that Pasteur may be said to have *discovered* microbes, and that was less than sixty years ago. When the wine and beer turned sour he found a foreign fungus had fermented them. When milk turned sour he found a microbe in the pail. When the silkworms withered he found a parasite within them. When the chickens died of cholera he found a bacillus at work, and when the cattle died he found the long chains and whorls of anthrax in their blood. When the women died of childbed fever he found the streptococcus; and when the Alsatian peasant child, Joseph Meister, bitten by a rabid dog, was brought to him, he inferred again a microbic origin for rabies and cured him with a vaccine.

You notice that Pasteur used the very word *vaccin*, because though no microbe had then, nor has since, been found for "small-pox," he felt that the immunity he was able to confer with his injections of enfeebled or attenuated microbes must be the same as Jenner had conferred against small-pox by inoculation of the children with material taken from the disease of calves, known as cowpox; for that in fact is what we do in the process of ordinary vaccination.

Vaccinia or cowpox is either small-pox modified by passage through a calf, or an independent, but closely allied, affection. So closely allied is it that an attack of it, or what comes to the same thing, inoculation of the fluid taken from the cowpox vesicles into a human being protects him from catching small-pox. Hence the word "vaccination." In the light of our present knowledge it is safe to assume that in vaccination we are planting the germs of disease in an attenuated form upon the child, the result of which is to produce a temporary local sore, the vaccination pock or vesicle, and at the same time a lasting constitutional change, which protects the child from catching either cowpox or small-pox for seven years or more.

It may not be out of place to remark that when surgical cleanliness is observed, and "calf lymph" only used, the inoculation of any disease other than "cowpox" is impossible. The infections dreaded by those who know no better are those associated with the presence of the tubercle bacillus and the spirochæta pallida. Now the latter organism cannot be engrafted upon cattle. They are naturally immune to it, and places like the Pasteur and Jenner Institutes see to it that the calves used are absolutely free from tubercle or any other disease. Where there is nothing to be feared from an overdose of tuberculin, the test is practically infallible. Ordinary minor infections are prevented by the glycerine in which the vaccine lymph is carried.

But to return to Pasteur. It was while working with cultures of the microbe of chicken cholera that he accidentally stumbled upon artificial immunity. What he was trying to demonstrate at the time was that some bacilli which he had found swarming in the bodies of chickens dying from a cholera-like disease were actually the cause of the disease, because if these bacilli were sprinkled on the bread with which the chickens were fed they invariably sickened and died of chicken cholera.

One day on returning from an unusually long holiday he repeated his experiment; but for the first time the experiment, in a sense, failed. The chickens did not take the disease. The hitherto deadly culture had failed to kill. He tried again with a fresh culture from a recently fatal case, and still these chickens would not die, whereas this fresh culture killed fresh chickens every time.

What had happened? The old culture "attenuated" by age, had lost its death-dealing powers, and had acquired instead the priceless property of conveying immunity. Further investigation showed that the degree of virulence of the microbe varied directly with the age of the culture, and that the sub- or daughter-cultures "bred true," through successive generations, not only in the matter of virulence, but in the quality of the immunity they might be made to confer.

Here then, at last (to quote Mr. Stephen Paget), "was the living agent of disease—the thing itself, the real offender—corked up in a test tube," no longer a nameless horror, but in the words of Roux' famous paper, "a thing that we could turn this way and that—stuff so plastic that a man could work upon it and fashion it to his liking."

The import of these observations was that microbes, as a source of disease, were not a blind force like lightning, but like the current from a battery, could be controlled at will, could be made to kill outright, as in the fulminating types of disease, or dealt out with a fractional part of their original strength and even made to become—next to the *vis medicatrix nature* itself—the most potent curative force known to science. With these historic discoveries of Pasteur the science of therapeutic immunisation was born.

Jenner had immunised with his vaccine, it is true; but at that date—1796—the connection between bacteria and disease was not dreamt of, and his method of conveying cowpox to prevent small-pox was only one step removed from conveying the disease itself.

It was not quite a blind shot—for he had tradition to guide him—and it hit the mark; but it seemed to be an isolated incident leading nowhere; and for nearly a hundred years no progress was made.

Pasteur's discovery was the first link in a chain, and it was not long (1881) before he unearthed the whole mystery of the prevailing cattle plague—anthrax—and working on the same lines, cured some and protected others by a vaccine. In 1885 he protected a child against rabies by using a vaccine made from the spinal cord of a rabbit, the virulence having been lowered by "drying" instead of by mere lapse of time. This was the great personal triumph of Pasteur's life, and the story of it is splendidly told in his biography—a book which every educated man and woman ought to read.

It is not my purpose to weary you with a bald list of the discoveries which resulted directly from Pasteur's work. An example taken here and there will be enough.

In 1881 Koch had discovered the bacillus of tuberculosis, and showed it to English doctors at the International Medical Congress in London. In 1890 he announced to the world that in tuberculin, another vaccine, he had found the remedy. In that very year came the news that animals could be immunised against diphtheria and tetanus just as against anthrax and rabies, and the discovery of a cure for tuberculosis was confidently expected.

When Koch's announcement came, no one who had followed the march of events doubted the value of his method. Was he not Pasteur's most distinguished pupil? Had he not made discoveries of first-class importance himself? It was he who had found the tubercle bacillus, and his work on cholera was a monument to his genius. The term vaccine was a word to conjure with. And yet his vaccine failed miserably, and apparently hopelessly. Some men who tried it said it actually killed their patients. The hopes of the consumptive were dashed to the ground. As Mr. Paget says: "The failure of tuberculin was one of the world's tragedies," and vaccine treatment for tuberculosis came to a standstill.

There was no doubt, however, about the value of the anti-toxin serum against diphtheria and tetanus or "lock-jaw." In both cases, if given before severe symptoms developed—that is in the first two or three days—the effect was magical and protection absolute.

With the most brilliant minds the world over now focussed upon the whole question of immunity, fresh successes in the field of preventive medicine were soon forthcoming; the natural histories of malaria, yellow

fever, Malta fever, and plague read like fairy tales. Protection could be given against cholera, typhoid fever, dysentery and plague by means of vaccines; yet tuberculosis lagged, and still lags, behind.

It was natural that men should want to know the reason why; and countless experiments have been made into the nature of immunity, and although some light has been thrown on the process, it still abides in the main an inscrutable mystery.

In 1883 Metchnikoff had propounded his well-known phagocytic theory of immunity, according to which the white cells in the blood were said to engulf and destroy the microbes.

This theory was followed by a humoral theory. Here the fluid constituents of the blood are supposed to play a more important part in destroying the microbes, while the blood cells only clear away their dead and mutilated bodies.

All sorts of views were held—many more or less fantastic—but, amid a conflict of opinion, Wright, a countryman of our own, stepped into the field with one prime factor established—namely, that, whatever other protective elements might or might not exist in the blood, there was one, which he called "opsonin," and which was called into being in variable quantity under the stimulus of microbial infection.

This substance acts upon the live microbes—or, as he put it, prepares them as food for the blood cells—so that more microbes are engulfed than otherwise would be the case. He established the fact that when the dead bodies of these very microbes were injected into the blood in suitable doses, the amount of this substance was markedly increased. There followed a sort of high tide of "opsonin" in the blood, and during its flow many bacteria were killed and engulfed. This tide ebbs and flows, and during the ebb the microbes make headway. He found, moreover, that this tide might be controlled to a great extent; that the ebb or flow depended upon the *size* of the dose and the *interval* between the injections, and he invented a method for determining the correct dose and the time at which it should be given to ensure the best result. He learnt, too, by experience, that if the dose was given at the wrong time, or was too large, the tide fell often to an alarming or even fatal level.

Here, then, was at least one reason why Koch's tuberculin had failed. There was no method available for finding out anything about it beyond what could be gathered from the condition of the patient himself; and when tuberculin was first put on the market there was a rush made for it. It was given ignorantly—by ignorant people—with desperate results alike to the patients and to the authors of the method. It was a "joy-day" for the anti-vivisectionists.

As Wright's work extended, it was found that this substance, "opsonin," was specific for each individual kind of microbe—that is to say, each separate kind of microbe produced its own peculiar kind of opsonin, protective against that microbe and against no other.

Further, an opsonin rise could be induced against almost every known microbe, whether disease-producing or non-disease-producing, and even against such "quasi-vegetable" growths as "actinomyces," or ray-fungus, and the pollen of plants.

Here was a weapon which, in skilled hands, might be used effectively against the whole range of infective disease, provided the microbe could be found.

This was Wright's idea. It was a grand conception, and he forthwith proceeded to carry it out and set about preparing his vaccines.

Wright's vaccines are not such as are used for small-pox or rabies, which consist of material carrying a living, attenuated, but as yet unknown microbe. They are doses of the microbes known to be the particular cause of the disease in question killed by heat and injected in known quantities.

In order to find the microbe, material, such as "matter" from a boil, phlegm from bronchitis, or blood from a vein, is taken and "sown" upon a surface of sterilised jelly, made from seaweed, exactly as you might take a handful of chaff mixed with

various seeds and sow it on prepared ground in your garden. In the course of a few hours the germs grow in little colonies, and a bacteriologist can often name the microbe by the naked eye appearance of its growth, just as a gardener will name the seedlings in a potting shed.

All bacteriologists and all gardeners are not equally skilful. Some gardeners will take the most unlikely thing and apparently plant it just anyhow, and it grows to perfection. Others, with infinite care, only succeed as it were by accident; and so it is with bacteriologists—"Non cuius homini contingit."

Having obtained a sufficient growth of the desired microbe in pure culture in a tube, the bacteriologist washes it off the jelly with salt water, and shakes it thoroughly to form a uniform suspension of the microbes. The number of microbes in a measured quantity of this suspension is now counted under a microscope, and the whole suspension, in a hermetically-sealed glass tube, is killed by heating in a water bath. This, then, is the vaccine, and when it has been proved, by sowing a little of the suspension on a fresh sterile tube of jelly, that the microbes are all dead and incapable of producing any disease when injected, it is ready for use. To make assurance doubly sure a drop or two of carbolic acid is added to the stock of vaccine.

It sounds a simple process, but it demands infinite patience, useful hands, and absolute honesty in work, and any man (I speak to the students) who undertakes to make vaccines without these qualifications is a danger to society.

When Wright began his work he found that some infections yielded less readily than others, but in many his success was immediate and startling. Working patiently, with his distinguished colleague, Douglas, and guided ever by his own peculiar "touchstone"—the opsonic index—he attacked, syringe in hand, the infections one after another—tubercle (hydra-headed), typhoid, pneumonia, bronchitis, asthma; sepsis in its myriad forms, including peritonitis, septicæmia, childbed fever; and even such lesser ailments as "toothache," "cold in the head," hay fever, boils and blains, and "black-heads." Surely a formidable list, and yet by no means complete.

It was a giant's task, one to fire any man's imagination. It is the direct continuation of Pasteur's own work, and it has been given to an Irishman to carry on the torch.

Let it be noted that in the field of medicine, especially of preventive medicine, every great step forward of recent years has been due to the work of pathologists. What is the value of the delicate handling of a drug or combinations and permutations of drugs compared with work which has made small-pox almost a thing forgotten, which has swept Malta fever from our armies and navies, which has protected regiments against typhoid fever, and made possible the cutting of the Panama Canal by abolishing malaria and yellow fever?

Already great strides have been made against many of the most horrible forms of tuberculosis.

When vaccines do their work they cure without scarring and without deformity. As it is, many nearly blind have been given back their sight, and, as Wright says, it is only a matter of time before the high-booted cripple and the hunch-back shall disappear from our streets.

There is hardly a known form of infective disease in these islands against which Wright has not battled, and met with a large measure of success. Here is a short extract from the report of his department published this summer (1912):—

"Many a grim story of struggle against long odds has come to light in this department. For it has happened, not unnaturally, that our advocacy of a new system of treatment has evoked a challenge to demonstrate its utility *first* upon the most difficult class of patients—the undesirable of every general hospital, the unresponsive to every form of treatment. Here we have in mind, not so much consumptives, and those whose span of life can be foretold in months, but that considerable class on whom tuberculous cr

other disease makes less impetuous claims, sparing the lungs, but quietly destroying, scarring, crippling other parts of the body over a period of many years. A dozen faces immediately come to memory—children and young adults—who, when they came to the department, could recount already a series of ten or twenty adventures with surgery, and whose few years, despoiled of schooling and employment, had been spent nursing one part after another back to some degree of health."

How familiar is this picture of all of us who know the "Smyly Ward" and the extern department of this hospital, and when we hear men decrying the vaccine treatment of tuberculosis, let us remember that a leading physician had his life-long opposition to vaccination for small-pox engraved upon his tombstone.

There is one drawback to Wright's method, and that is the difficulty of using his touchstone—the opsonic index. He and his school know how to use it, and use it daily. In their hands it seems unerring. But many, even skilled bacteriologists, have not met with the same success, and the very existence of his "opsonin" has been scoffed at by lesser men. Yet think what the "index" has admittedly accomplished. Without it tuberculin treatment would not yet have been revived at all. And those who would relegate the "index" to the limbo of anachronisms forget that to it they owe their knowledge of the dosage of those other vaccines now in daily use.

This "index" has another priceless faculty—it can be made to work backwards. By its delicate response to the stimulus of microbic infection it can be made to indicate which of many is the real offender, and having pointed him out, it tells you what dose is most likely to destroy him. For the successful treatment of the more severe forms of tuberculosis, a knowledge of the working of the index is at present a *sine qua non*. There are many cases of that exquisitely painful condition vesical tuberculosis that have been set back indefinitely by a single incautious overdose; and, mind you, the handling of tuberculin is a delicate business. The doses are measured in parts of a milligram of killed and ground-up tubercle bacilli, and a common dose is 1-10000th of a milligram—just as delicate a thing as exposing photographic plates, when the exposures are measured in 1-1000ths of a second. Similar caution is requisite in the treatment of pulmonary tuberculosis by vaccines. All sorts of considerations have to be taken into account, mainly dealing with the prevention of auto-inoculations by enforcing absolute rest. So difficult is it, and requiring such patience, that most practitioners have given it up altogether, and yet for many consumptives this method holds out the only hope of cure.

As Wright has pointed out, only about half the cases owe their low resistance to unhygienic surroundings, and these are the cases that may do well under ordinary rest, "fresh air," and sanatorium treatment. Of these, many show marked improvement under vaccination in spite of the most desperate surroundings, and *post-mortem* findings, as well as other evidence, goes to prove beyond doubt that many consumptives have got well without any treatment at all. The other half belong to the well-to-do, many of them living in the best possible surroundings, and still they suffer. For these there is nothing for it but inoculation.

In phthisis half the mischief is due to other microbes, two or three often working together side by side with the tubercle bacillus, and these have to be ferreted out and removed *seriatim*, each with its own appropriate vaccine. Yet this can be done, but it takes skill, patience, experience, and above all a conscience. The work demands enthusiasts, men of the highest type we can produce, men with ideals, not tradesmen, nor yet fledgling specialists let loose after a fortnight's incubation upon a wondering world.

If it is asked how is this work to be done, and where are we to get the men?—my answer is, "Here, among the students of medicine—qualified and unqualified—of the Dublin hospitals." There ought to be a vaccine department within the walls of this and every general hospital.

Vaccine treatment has been carried on here in a

tentative way—a very small beginning—but still something has been done, but it is crying out for organisation. There is a flourishing department at the Rotunda Hospital, under Dr. Rowlette's able management, and in the South London Union Dr. Dunne has already done fine work among the poor consumptives. But it is in the pathological laboratories of the general hospitals, in the wards, and in the extern departments that the best work alone can be done. The laboratories of the medical schools are not the places for it. For success we require not only the technical skill of the bacteriologist, but the experience, judgment, and second-sight of the surgeon and physician to read the signs aright. We must have sympathy and co-operation between the great departments. They have much to learn from one another.

In conclusion, I would remind you that in our own pathologist, Professor White, we have a man who was among the first in Ireland to take up the serious study of the new treatment; one, too, who has devised an original and admirable substitute for the all-too-intricate and tedious opsonic index—a method directly applicable to more than half the cases we should have to treat.

This old hospital was once in the very vanguard of the world's march against disease—let us no longer be camp-followers.

This is Pasteur's own work, and since the day when the Great Physician healed the sick in Galilee, no man has done so much for suffering humanity as Louis Pasteur. His motto was: *Il faut travailler*. Let us be up and doing, "for the night cometh when no man can work."

THE NEUROLOGY OF THE VISUAL SYSTEM.

A Short Series of Original Papers.

By HARRY CAMPBELL, M.D., F.R.C.P.;

Physician to the West End Hospital for Diseases of the Nervous System.

PAPER II.

Lacuna in the visual field.—A blind patch in the visual field is known as a *lacuna* or *scotoma*. In central scotoma the object fixed is not distinctly seen. In rare cases it may appear to be filmed over or covered by a dark patch, and the defect is then not due to interruption in the visual nervous path (*e.g.*, the retina or optic nerve-fibres) but to interception, by a small hæmorrhage or kindred lesion, of the rays of light between the surface of the retina and the layer of rods and cones. A lacuna of this kind is known as an *objective scotoma*.

Central lacuna or scotoma (Fig. 9) is most

FIG. 9.—The shaded area in each chart shows a central scotoma.

frequently observed in the amblyopia produced by tobacco, alcohol and diabetes. It may also result from a macular lesion.

In peripheral lacuna there is generally a concentric narrowing ("retraction") of the visual field. This form is most frequently met with in hysteria. Hysterical amblyopia is generally confined to the periphery of the field, but it may extend to the macular region, leaving only a

narrow zone of central vision; in rare cases even this is involved. The degree of narrowing is apt to change from time to time; it is more marked when the index is moved from the periphery inwards than when it is moved contrariwise; the narrowing generally involves colour vision in the normal order, but it may happen that the red field extends beyond the blue, sometimes, indeed, beyond the white. Sometimes a central scotoma occurs in hysteria with or without a concentric narrowing of the field. It is noteworthy that the patient is much less inconvenienced by hysterical amblyopia than by that which results from organic disease.

Concentric narrowing may also result from organic causes, *e.g.*, disease of the optic nerve, retinitis pigmentosa, and glaucoma.

It may happen that peripheral and central vision are normal, leaving an intermediate annular lacuna. Irregular peripheral lacuna may result from disease in the optic tracts, optic nerves, or retina.

Defective perception of colours.—The ability to perceive colours may be lacking (achromatopsia), or curtailed (dyschromatopsia).

In cases of gross organic defect (*e.g.*, microcephaly) there may be complete congenital colour-blindness. More frequently, however, congenital colour-blindness is partial (Daltonism). It generally involves red and green, only exceptionally yellow and blue. In the red-green varieties, green and blue are the only colours seen in the spectrum; red is confounded with grey or white, green with gray or white, red with green.

Colour vision may likewise be affected by acquired disease. Disease of the retina may cause colour-blind lacunæ: retinitis pigmentosa may cause a considerable narrowing of the visual field for all the colours, even for white; and the same is true of glaucoma. Optic neuritis and optic atrophy may lead to considerable achromatopsia. In the retro-bulbar neuritis resulting from poisoning from nicotine or alcohol, central scotoma, first for green, then for red, and finally even for white, may occur. Hemi-achromatopsia has been described in connection with disease of the occipital lobe, but cases of this kind are probably instances of ordinary hemi-anopsia in which colour vision is involved. Hysterical colour-blindness has already been referred to.

Colour-blindness is tested as follows: A number of duplicated coloured wools are used. One is chosen and the patient is asked to match it. The examination should not be conducted by artificial light, but by bright daylight. The patient is not asked to name the colour: he may name it correctly, although he may not perceive the colour rightly; *e.g.*, a red-blind person, who sees red as brown, may correctly call it red, because he is accustomed to hear it so called, but his perception of the colour is not the same as that of a person with normal vision.

AMAUROSIS AND AMBLYOPIA.

The terms amaurosis and amblyopia are generally employed to denote defects of vision without any discoverable ocular defects (error of refraction, opacity of the cornea, or lens, retinitis, optic neuritis or atrophy) to account for them. The term amblyopia denotes a partial blindness of this kind; amaurosis, complete blindness.

Bilateral hysterical amaurosis.—A rare condition. There is complete blindness. The pupillary reflexes are preserved and the defect has all

the characters of cortical blindness. It may last a few days only, or some weeks. It may come on and it may terminate either gradually or suddenly.

Unilateral hysterical amaurosis.—There is almost always hemi-anæsthesia on the side of the blind eye. The visual field of the opposite eye is often concentrically narrowed. The amaurosis may only be present when the opposite eye is covered, the amaurotic eye functioning normally in binocular vision.

Hysterical amblyopia.: This is the most common visual defect in hysteria. Vision is generally lost in the periphery of the field (retraction of the visual field), but sometimes central vision is likewise affected. There may be defect as regards colour vision. These hysterical defects of vision may go along with retinal hyperæsthesia (photophobia) which may also occur independently of visual defect.

Reflex amblyopia.: Neuralgia of the fifth nerve (*e.g.*, from dental caries) may cause transitory visual defects, largely perhaps by disturbing accommodation. The older writers frequently refer to intestinal worms as a cause of visual disturbance, though without convincing evidence. Temporary visual defects may result from disorders of the reproductive organs; but it is doubtful whether the causal connection is reflex.

Toxic amblyopia.: The toxæmia caused by tobacco, alcohol (acting singly, or—more frequently—in conjunction), and diabetes induces amblyopia by setting up retrobulbar neuritis. Central vision is affected, the perception of green and red being first lost. Visual acuity may be reduced to 1/10, or even beyond this. In all but the extreme cases of amblyopia caused by tobacco and alcohol, normal vision can be recovered, provided the cause be removed. Among the other poisons which may set up amblyopia are lead, opium, belladonna, quinine, salicylate of soda, and bisulphide of carbon. In the case of lead, optic neuritis and optic atrophy may occur.

Uræmia may induce blindness lasting from a few minutes to several days.

Amblyopia from disuse.—When in strabismus one eye is mainly or solely used in fixation, the other eye may lose the power of seeing distinctly. Such is frequently the case in non-paralytic strabismus of children. Normal binocular vision can be regained in these cases by re-education.

Other causes of amblyopia are profound anæmia, syncope, and fever. Occasionally sudden and complete amaurosis of a few days' duration occurs in apparently healthy people without discoverable cause.

Night blindness.—In this condition vision is good in a bright light, but almost completely fails in the dusk. Night blindness is most frequently met with in retinitis pigmentosa, and is generally congenital, increasing with age. It may, however, occur temporarily in debilitating diseases.

Summary of the effects produced by lesions in different parts of the sensory visual tract.—Except where otherwise stated, a destructive lesion is implied. (Fig. 10.)

Optic nerve and the retina: Visual defect in the corresponding eye.

Optic chiasma: Heterolateral hemianopia—*i.e.*, blindness in both nasal, or both temporal, halves of the retina: or of one nasal or one temporal half.

Hemioptic tract (optic tract, pulvinar, external geniculate body, retro-lenticular part of the

internal capsule, optic radiations, peri-calcarine hemiopic cortex): Homolateral hemianopia—*i.e.*, blindness of the corresponding lateral half of each retina. If the lesion is in the optic tract there is likewise hemiopic loss of the light reflex (Wernicke's sign). A small lesion internal to the external geniculate body, by interrupting the

FIG. 10.—Diagram showing sensory visual tracts: 1, optic nerve, 2, optic commissure, 3, optic tract, 4, corpus geniculatum externum, 5, pulvinar, 6, retro-lenticular portion of the internal capsule, 7, optic radiations, 8, hemiopic cortex. Destructive lesions in these several parts cause: of 1, blindness of the corresponding eye, of 2, heteronymous hemianopia, of 3, 4, 5, 6, 7, or 8, homogeneous hemianopia. When lesion is in 2 (?) or 3, Wernicke's sign is present. A bilateral lesion in 8 causes double hemianopia with retention of macular vision.

hemiopic light reflex fibres after they have left the visual fibres may—theoretically at least—cause hemiopic loss of light reflex without hemianopia.

Retro-lenticular part of the internal capsule: The hemianopia occurs as an adjunct to hemiplegia with hemi-anæsthesia. If the lesion is left-sided, word-blindness may also be present, from involvement of the left angular gyrus.

Supra-calcarine portion of the hemiopic area (cuneate lobe): Blindness of the corresponding (*i.e.*, left or right) upper quadrant of each retina—quadrantic hemianopia. If such a cortical lesion is bilateral: blindness of the entire upper half of each retina (horizontal hemianopia).

Infra-calcarine portion of the hemiopic area (lingual gyrus): Blindness of the corresponding lower quadrant of each retina. If the cortical lesion is bilateral: Blindness of the entire lower half of each retina (horizontal hemianopia).

Hemiopic cortex, bilateral: Double hemianopia with retention of macular vision.

Irritative lesion of hemiopic cortex: hemiopic visual phenomena—*i.e.*, visual phenomena referred to the opposite side of the sagittal plane.

Left angular gyrus: Word-blindness.

Right angular gyrus: No effect capable of being diagnosed.

Both angular gyri: Total blindness.

Irritative lesion of angular gyrus: Visual hallucinations or simple visual sensations.

The effects of lesions in different portions of the sensory visual tracts will now be considered in detail. These lesions fall into the following groups:

A. Lesions of the retina and optic nerve.

B. Lesions producing hemiopic effects. Such are situated in the chiasma, the optic tract, the corpus geniculatum externum, the retro-lenticular portion of the internal capsule, the optic radiations, or the hemiopic cortex.

C. Lesions of the angular gyrus.

A. LESIONS OF THE RETINA AND THE OPTIC NERVE.

A destructive lesion in either the retina or the optic nerve of one side causes blindness of the corresponding eye. In no other region can a single lesion cause unilateral blindness. (Unilateral hysterical amblyopia may occur, but this is very rare.)

Lesions of the retina.—There is no need to enumerate all the various affections of the retina which may affect vision. Sudden loss of sight in one eye may result from embolism of the central retinal artery. In this case sight may be regained in a part of the retina if the circulation has not been completely arrested. Hæmorrhage into the retina may cause sudden loss of sight. The failure of vision which occurs in connection with megrim is possibly due to spasm of the retinal vessels. Such spasm has been observed at the initial phase of the seizure, when visual symptoms are so frequent. It is probably one of the causes of transient blindness and of so-called "reflex amblyopia."

Lesions of the optic nerve.—The chief are optic neuritis and optic atrophy.

Optic neuritis.—This may be intra-bulbar or retro-bulbar. The former can be detected by the ophthalmoscope; the latter cannot.

Intra-bulbar neuritis (papillitis).—The inflammation involves the nerve as far as its termination at the sclerotic ring, where, as seen by the ophthalmoscope, it appears as the "disc."

The effusion causes the disc to swell: in some forms of optic neuritis the disc may be raised six or eight diopters and its diameter increased to twice or thrice the normal, even causing the adjacent retina to be detached and thrown into concentric folds. The capillaries of the disc are congested, but it must not be forgotten that mere redness of the disc is no evidence of neuritis. The veins are distended; hæmorrhage into the disc and adjacent retina may occur and the vessels may in varying degrees be hidden by the inflammatory effusion. Most characteristic of all is the blurring of the disc edge. In the less intense forms the disc presents a soft, woolly aspect, and the veins are much distended. The causes of intra-bulbar neuritis may be grouped as follows:—

Tumour (cyst, hydatid, aneurysm): The neuritis is often intense. It occurs most frequently in malignant tumour and gumma. It often occurs first and most markedly on the side of the tumour. It tends to subside on decompression, showing that increased intra-cranial pressure plays some part in causation.

Meningitis: The neuritis is rarely intense, and is most apt to occur in the basal form. In meningitis involving the cavity of the brain optic neuritis tends to appear as a later development, but it may not occur at all.

Abscess: The neuritis is not usually intense. It occurs in about two-thirds of the cases.

Toxics: Bright's disease, Lead poisoning.

Infections: Scarlatina, Chorea, Enteric fever, Measles, Influenza, Malaria, Syphilis.

Anæmias: In severe anæmias (*e.g.*, pernicious anæmia, leucæmia) besides actual hæmorrhages, slight neuritis may occur. Both of these are rare in chlorosis.

Retro-bulbar neuritis.—The inflammation involves the optic nerve behind the globe. It may occur without any discernible alteration in the disc. The causes of retro-bulbar neuritis may be classified as follows:—

Compression: Direct compression of the optic nerve (*e.g.*, by tumour) may set up retro-bulbar neuritis (see causes of secondary optic atrophy).

Toxics: In tobacco-poisoning, chronic alcoholism, gout, and diabetes, there may be neuritis, chiefly of the central macular fibres.

The Manifestations of optic neuritis.—The changes in the disc in the intra-bulbar variety have been described. When in the retro-bulbar variety the disc is not involved it appears normal. Complete blindness is rare. Short of this, there may occur a narrowing, irregular or concentric, of the visual field, with central scotoma, dischromatopsia, and achromatopsia. In the toxic forms of retro-bulbar neuritis, in which the brunt of the inflammation is apt to fall upon the macular fibres, central scotoma, especially for colours, is common.

Optic atrophy.—This may be primary or secondary.

Primary optic atrophy occurs independently of neuritis or external pressure. It generally results from toxic action. It may be congenital or familial (coming on, *i.e.*, in several members of the same family).

Secondary atrophy is that which occurs secondarily to some gross organic lesions, such as neuritis (whether intra-bulbar or retro-bulbar), or to one causing compression of the optic nerve, the chiasma, or the optic tract. (Some writers designate the atrophy which follows upon intra-bulbar neuritis "consecutive," limiting the term "secondary" to that form which results from disease implicating the retro-bulbar portion of the nerve.)

The following are the chief conditions under which optic atrophy occurs:—

Primary: In Tabes, in about fifteen per cent. of tabetic patients, constituting about one-third of all cases of primary atrophy; it is always bi-lateral and may remain all but an isolated symptom for years, causing false Argyll-Robertson pupil.

In Syphilis, but it is rare apart from tabes.

In Lead poisoning, very rare.

In Amaurotic idiocy; met with in idiots in connection with characteristic changes in the macular (here is seen a shiny red spot—the result of local œdema and atrophy of the retina).

Familial: Several members of one family are affected. A toxic factor (*e.g.* tobacco) may co-operate in causation.

Secondary: as a sequel to intra-bulbar and retro-bulbar neuritis, and to compression of the optic nerve, chiasma, or tract, with or without neuritis. Such compression may result from tumour (especially of the pituitary body), distension of the third ventricle, narrowing of the optic foramen and intra-orbital cellulitis.

The optic atrophy met with in disseminated sclerosis (present in about forty per cent. of the cases) is generally a mild form. It results from the involvement of the nerve in one of the fibrous nodules which characterize this disease. Should the nodule be situated near the disc it may give rise to the appearance of optic neuritis.

The manifestations of optic atrophy.—The disc is unduly pale from capillary atrophy, varying in aspect from grey to glistening white, but it should be noted that inasmuch as the redness of the disc normally varies considerably in degree in different persons, it may not be possible to diagnose minor degrees of atrophy from its colour. In a well-marked case, the edge of the disc stands out sharply against the surrounding coloured area. The calibre of the arteries and veins may be reduced, in which case the retina is correspondingly atrophied, allowing the vascular choroid to shine through. In the primary form the disc is hollowed out, not merely in the region of the central cup, but right up to the sclerotic rim. In the secondary form it is more apt to have a "filled-in" appearance. In this form also the atrophy is rarely so marked as in the primary.

The effects on vision of optic atrophy are much the same as those of optic neuritis. There is no necessary relation between the degree of pallor and of visual loss. In a disc originally pale, complete pallor is consistent with the retention of some degree of vision. In the early stages of atrophy following upon intra-bulbar neuritis, the sight gets progressively worse, but may subsequently improve somewhat owing to the recovery of some of the nerve-fibres. In many forms of primary atrophy (*e.g.*, the tabetic variety) the visual field tends to diminish from the periphery inwards, although central scotoma, especially for colours (which may be the first visual defect to show itself), may be present in the atrophy occurring secondarily to retro-bulbar toxic neuritis. Different varieties of hemianopia, including the quadrantic form, may occur in atrophy secondary to lesion in the chiasma.

While hemianopia practically always indicates a lesion of, or behind, the optic chiasma, it may occasionally happen that the fibres of the optic nerves (*e.g.*, in optic atrophy) are so picked out as to cause blindness in one half of each eye—either corresponding, or non-corresponding halves; but this never happens as exactly as when the lesion involves the chiasma or the hemiopic tract behind it. Horizontal hemianopias are by some, attributed to symmetrical lesions of the optic nerves.

(To be continued.)

OPERATING THEATRES,

KING'S COLLEGE HOSPITAL.

ARTHROPLASTY.—MR. ARTHUR EDMUNDS operated on a man, æt. 35, who had been admitted suffering from a badly united fracture of the lower end of the left humerus with complete fixation of the elbow joint. The fracture extended through the articular surface, was comminuted, the fragments being displaced inwards so that the lower end of the shaft formed a projection underneath the skin on the outer side. Pronation and supination were free, but flexion and extension were entirely lost.

An anæsthetic was administered, and the arm forcibly moved, but it was found that movement was taking place entirely through the site of the fracture, which broke down readily. An incision was then made along the outer border of the forearm externally from a point about three inches above the projecting portion of the shaft down to the line of the joint, and then inwards across the back of the joint to the level of the internal condyle, thus marking out two sides of a quadrilateral. The skin over this area was then raised, the flap turned up, including only the superficial half of the fatty tissue, the inner portion of the quadrilateral being separated by undercutting at the same level. The incision on the inner side was next

deepened, the joint opened, and the humerus turned out into the wound. The loose fragments of bone were removed, and the lower end of the humerus fashioned so as to resemble as far as possible the normal lower extremity of this bone, which it was found possible to do without dividing the internal lateral ligament. The skin over the quadrilateral area was then retracted, and a flap cut consisting of the deep fascia and the deeper half of the fatty tissue. This was raised except at the lower border, where it was left attached. It was considered desirable, Mr. Edmunds said, to raise the flap by this method of undercutting, rather than by turning a flap up boldly, in order to minimise the risk of sloughing, which is undoubtedly present in such thin flaps. An incision was finally made through the tendon of the triceps and the flap of fascia drawn through this into the joint cavity, where it was sutured to the periosteum over the humerus. The wound was then closed, a drainage tube being inserted at the upper angle for twenty-four hours.

Mr. Edmunds said that from the results which have been obtained by Murphy's method of dealing with ankylosed joints, it seems probable that this operation will take a permanent place in surgery, although the limits of its usefulness are not exactly defined. In the elbow it is usually preferable to take a flap from the side of the limb, but he pointed out that the projecting portion of the shaft had thinned the skin so much that it did not seem practicable to make a flap from this region in the present case. The nutrition of the flap which is interposed between the bone surfaces must always, he thought, be precarious, and it is just possible that equally good results may be obtained by covering the ends of the bone with completely detached pieces of fascia prepared exactly as he had already done and sutured over the periosteum. The principles of the operation, he remarked, are to restore roughly the bone surfaces and to interpose a flap of fascia containing fat, as it is in adipose tissue that an adventitious bursa can be most readily formed and play the part of a new joint cavity. Details of the operation, however, Mr. Edmunds pointed out, must be devised for each case.

The wound healed normally, and then passive movements were commenced, at first under an anæsthetic, and later without one. Active movements were impossible without assistance, the muscles having undergone an extreme amount of wasting before the operation, a fact that has been a considerable drawback in the after treatment of the case. The case is still under treatment, and it is impossible to say what the ultimate functional result will be, but provided the muscles recover there is every reason to hope that a satisfactory limb would be obtained in the end.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, NOVEMBER 22ND, 1912.

The President, Mr. A. H. TUBBY, F.R.C.S., in the Chair.

EXHIBITION OF CASES AND SPECIMENS.

Dr. J. L. BUNCH showed a Congenital Syphilitic Infant treated by Intravenous Injection of Neo-salvarsan. The child, a girl, was 2 years old, and was suffering from an offensive muco-purulent discharge from the nostrils, malnutrition, and well-marked condylomata round the anus. The Wassermann reaction had been markedly positive, and on October 30 she was given a dose of 0.45 gm. neo-salvarsan intravenously into the median basilic vein. No ill-effects of any kind followed the injection. The child left the hospital two days afterwards with the syphilitic symptoms greatly improved, and a week afterwards the condylomata and muco-purulent rhinitis had disappeared.

On November 13 a second injection of neo-salvarsan was given, this time intramuscularly into the right

buttock. The amount of neo-salvarsan so injected was again 0.45 gm. The child had steadily improved in general health and had put on weight. The Wassermann reaction was negative.

Dr. WALTER CARR showed a case of Partial Hemiatrophy of the Face and Tongue. Boy, æt. 9 years. About a year ago the patient's mother first noticed a whitish spot, like a scar, over the lower border of the lower jaw on the right side. Since then a gradual wasting of the lower part of the right side of the face had been observed. No cause could be assigned for the onset of the atrophy; there was no history of illness or of trauma. When shown there was marked atrophy of the skin, subcutaneous tissues and muscles over and below the right half of the lower jaw, from the angle to the symphysis. The bone itself also appeared to be somewhat wasted, but an X-ray examination did not show any definite atrophy. The skin showed slight, rather patchy atrophic changes; its sensibility was unaltered, except perhaps for a very slight diminution to touch. The muscles contracted normally, those of mastication were not affected. There was marked atrophy also of the right half of the tongue, but no affection of movement, ordinary sensibility, or taste. In all other respects, except for slight psoriasis, the boy seemed quite normal, both physically and mentally.

Mr. LIONEL E. C. NORBURY showed a case of Spina Bifida (Meningo-myelocoele) treated by Operation. The girl when aged 5 weeks, was admitted with an ulcerating sacral spina bifida, the size of a large tangerine orange. There was very little true skin over the swelling, the covering consisting chiefly of a thin membrane, discharging in several places. There was a slight degree of hydrocephalus; talipes calcaneus bilateral; no other paralyses. After the ulcers had healed an operation was performed under chloroform anæsthesia of excision of the spina bifida by elliptical incisions. A rubber tube was stitched into the rectum to avoid soiling of the wound, but did not remain in position very long. The child was kept in a slanting position with the head low, until the wounds had healed. There was never any leakage of cerebrospinal fluid during convalescence.

The child was 16 months old when shown. She was intelligent. The anterior fontanelle was almost closed. There was no bulging in the region of the wound. The condition of talipes calcaneus remained and was being treated by massage and passive movement by the mother.

Mr. H. A. T. FAIRBANK showed a case of Ununited Fracture of the Neck of the Femur. The patient, a girl, aged 15, gave a history of having been knocked down and run over by a van in October, 1904. The diagnosis was said to have been "comminuted fracture of the femur near the neck." The left leg had always been short since the accident, which necessitated her lying in bed many weeks. The shortness was said to be increasing. Pain had been present at times only, but had been worse lately. The pain was severe at night, it wakened her; it was particularly noticeable on rising after sitting for long, but it was not caused by walking except in wet weather. The left leg was wasted, and held in an everted position. Flexion of the hip was possible to a right angle only; abduction was practically abolished, while internal rotation was very limited; extension and adduction were only slightly limited. The trochanter was raised, prominent, and thickened anteriorly; the real shortening, 2 in. A skiagram showed an ununited fracture of the neck of the femur and coxa vara.

The case was shown in order to elicit opinions as to the best treatment. It was proposed to excise the head of the femur, and retain the limb in hyper-abduction for several weeks.

Dr. ERIC PRITCHARD and Mr. DOUGLAS DREW showed a case of œsophageal stricture. The patient was a boy, æt. 2 years, delicate from birth and subject to vomiting, and was admitted owing to inability to swallow solid food. He had been fed on liquid foods until recently, when inability to swallow solids was discovered. X-ray photograph showed a dilated œsophagus between the level of the suprasternal notch and xiphisternum and a stenosed portion below.

Dr. ERIC PRITCHARD also showed a case of multiple exostoses with wasting of the muscles of the upper arm. The patient was a boy, *æt.* 9 years. The first exostosis was noticed at the age of two years on the inner side of the upper end of the tibia. From that time until the present new exostoses had continued to develop, and were exceedingly numerous, especially in the ribs. For the most part they were symmetrical. There was considerable wasting of the muscles of the upper arm, but muscular power was good.

Mr. SIDNEY BOYD showed a case of osteoma of the forearm causing considerable deformity. A boy, *æt.* 9 years. The tumour of the forearm appeared to be growing from the ulna, and had caused considerable bowing of the radius. It was first noticed at the age of five years. The head of the radius was dislocated outwards. There was imperfect ossification of the lower end of the ulna, and a small tumour at the upper end of the same bone. He had also several osteomata on the ribs, one at the upper end of the right humerus, and one on the vertebral border of the left scapula. His father was said to have a bony tumour of the tibia. He was the ninth of eleven children. An elder brother, *æt.* 19 years, had a similar but smaller tumour of the forearm; it was said to have become much smaller, and caused no loss of function. Another brother, *æt.* 15 years, had a similar tumour, but it caused him very little inconvenience in his work as a typewriter. A sister, *æt.* 6 years, also had multiple osteomata.

Dr. G. A. SUTHERLAND showed a case of cerebral non-development. A girl, *æt.* 7 weeks. When aged two weeks convulsions came on in the form of irregular twitchings of face and limbs. Difficulty in swallowing was noticed. The breathing at times was rapid. The baby was fairly well nourished, the skull and other parts of the body appearing to be proportional in size. She lay in a completely apathetic condition, without smiling or taking any notice when awake, but could be roused to make certain gross movements of the trunk and limbs, although insensitive to pin-pricks. There was marked opisthotonos, with a tendency to left-sided pleurothotonos, and the limbs were in a spastic condition, flexion being present at the elbows, and extension at the knees. The hands and feet were in a condition of tetany. Other symptoms: (1) As a rule unable to suck or swallow; (2) attacks of tachypnoea, the respirations running up to 160 per minute, and being cyclic in character; (3) attacks of tachycardia, the heart-rate running up to 200 per minute; (4) fits of crying, causeless, beginning and ending abruptly; (5) spells of yawning; (6) occasional twitching about the face and hands, but no definite convulsive seizure. Fundi normal. Wassermann test negative. Cerebrospinal fluid scanty but normal; temperature normal.

It was suggested that the underlying condition was one of non-development of the cerebral lobes, and that only the cerebellum, pons, medulla, and basal ganglia were active. The uncontrolled action of these lower centres would explain most of the symptoms present.

Mr. H. S. CLOGG showed a case of malformation of the rectum (complete absence of the post-allantoic gut and the proctodæum); operation; result. A boy, *æt.* 4½ years. When five days old he was admitted to the Evelina Hospital. The abdomen was greatly distended; vomiting was frequent; there was entire absence of development of the proctodæum, without any indication where the bowel terminated. Immediate colostomy in left iliac region was performed.

When he was six months old an exploratory operation was performed from the perineal aspect. The bowel ended blindly at the level of the base of the prostate gland, to which it was adherent: it was separated from the prostate and sufficiently mobilised to enable it to be brought to the perineal skin without tension, to which, after opening, it was sutured. To render access easier a portion of the coccyx was removed. In order to mobilise the bowel the peritoneum had to be freely incised, and several resistant peritoneal and connective tissue bands had to be severed. The wound healed satisfactorily without any retraction of the bowel. The colostomy was closed later.

When shown the bowel was seen to be united to the skin of the perineum; there was no stenosis nor prolapse; the motions were passed unconsciously; there was complete absence of sphincteric control.

The case was shown to illustrate (1) the advantages of an immediate primary colostomy over a perineal dissection in cases where the bowel ends at some distance from the perineum, for a deep perineal dissection in an infant, a day or two old, suffering from obstruction must be extremely difficult and probably fatal; (2) that in order to establish a perineal anus the bowel must be freely mobilised and brought to the perineal skin without tension, or very troublesome stenosis will result; and (3) the absence of sphincter control which is to be anticipated, since the sphincters are developed from the proctodæum. In this case there were a few fibres in the position of, and having the direction of, the external sphincter muscle, but as a muscle it could not be said to be developed.

Dr. O. K. WILLIAMSON showed a case for diagnosis. The boy, *æt.* 10, was brought to the hospital in April, 1912, on account of tremor of the head. The illness began three and a half years before this, when it was noticed that his hands trembled and that he had lost strength in them. After this a fine tremor was noticed in the head. Since this time he had been, on the whole, less bright mentally. He got more easily excited than before, was spiteful, and had been unsteady since the beginning of the illness, and he frequently fell. He had fits of bad temper. He improved for a time, but had been worse again of late.

There were coarse tremors of the arms, equal on the two sides, also of tongue; fine tremor of head; gait ataxic and reeling; he tended to fall to the left side; Romberg's sign absent; pupils reacted well to light and accommodation; hearing normal; doubtful slight lateral nystagmus; knee-jerks normal, no definite plantar response; speech was indistinct.

Dr. J. D. ROLLESTON showed a pharynx and larynx from fatal case of hæmorrhage from throat in a girl *æt.* 6. The specimen showed an abscess cavity in each tonsil, ulceration of the uvula, soft palate, epiglottis, frenum, epiglottidis valliculæ, and aryepiglottidean folds. There was deep ulceration of the laryngeal portion of the pharynx exposing muscular tissue. Three small superficial ulcers were present above right vocal cord. The exact site of the bleeding vessel was not determined, but there was no evidence of erosion of the parotid or internal jugular, or of any glandular abscess.

Dr. C. PAGET LAPAGE showed a primary carcinoma of the liver in a boy, *æt.* 6. The liver was considerably enlarged, with several rounded prominences on its anterior surface. The marked and progressive engorgement of the abdominal veins and the ascites showed that there was obstruction to the venous return in the region of the liver. There was no jaundice. The *post-mortem* examination showed that the liver was very large, weighing 6 lbs., the right lobe being chiefly affected by large masses of tumour, which were also growing into and obstructing the hepatic veins and inferior vena cava; there were secondary deposits in the lungs but nowhere else. Microscopical examination of the tumour showed polygonal and spheroidal cells in masses and columns, with very little stroma; the cell nuclei were oval or rounded, and showed many mitotic figures, and the cytoplasm was granular; there was much fatty infiltration.

There were bile-stained areas in the tumour masses and in the lung deposits, but not in the liver itself. The evidence for regarding this tumour as a primary carcinoma of the liver was twofold—viz., (1) the general resemblance of the cells to liver cells in form and arrangement, and (2) the resemblance in physiological function, as shown by the infiltration of fat and secretion of bile in both primary and secondary growths.

Dr. LEONARD GUTHRIE read a paper on
EPIDEMIC CATARRHAL JAUNDICE.

During the months of November and December, 1911, and January, 1912, the writer had met with ten cases of jaundice in children. Two or more members

of the same families had been affected in several instances, and the patients, with two exceptions, had lived in adjoining districts. Several of the patients were related as brothers or sisters. The ages of the patients ranged between three and eleven years. The liver was enlarged in six cases, and greatly so in four. Apparently all cases began with definite malaise and probably slight pyrexia, but none of the patients were seriously ill. No relapses occurred, and recovery was uneventful in all. Similar small and mild epidemics of catarrhal jaundice had been especially frequent during the last three years in this country and in many other parts of the world. A distinction should be drawn between it and Weit's disease. It was probably air-borne. The mortality was very low, but deaths had been recorded in other countries. The symptoms and pathology of the fatal cases were practically the same as in Weit's disease and in acute yellow atrophy of the liver. Epidemic catarrhal jaundice was regarded as a form of hepatitis, resembling mumps in some particulars, and not due merely to mechanical obstruction of the common bile duct, consequent to gastro-duodenal catarrh. Although no fatalities had been recorded in this country, the disease might at any time assume more serious proportions. The prognosis in any case should be guarded, and the question, "Is jaundice catching?" could no longer be answered by a direct negative. It was probably most communicable in its early febrile stage.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, NOVEMBER 8TH, 1912.

MR. R. D. PUREFOY, P.R.C.S.I., in the Chair.

CASES ILLUSTRATING THE OPERATIONS OF SYMPHYSIOTOMY, PUBIOTOMY, AND CÆSAREAN SECTION.

DR. E. H. TWEEDY exhibited a patient illustrating the three modern operations for the birth of the living child owing to contracted pelvis. Symphysiotomy was performed on one occasion, pubiotomy on another, and Cæsarean section on the last. When performing the Cæsarean section he tied the tubes, as he considered the patient had suffered enough at the hands of the surgeon. There was no material difference between any of the operations so far as the time occupied in bed or stay in hospital was concerned. The longest stay was three weeks and the shortest a fortnight. Symphysiotomy was a little more difficult to perform than pubiotomy, but he did not agree with the general idea that it was a painful and very difficult operation. The scar was about half an inch long instead of the pin-point scar of pubiotomy. There was not the slightest interference with locomotion, and the patient on being questioned declared that she did not mind any of the operations, and that she was as well able to walk as ever she was.

DR. SPENCER SHEILL asked if Dr. Tweedy could give the exact diameters of the pelvis in the case, as symphysiotomy or pubiotomy was usually applied in one class of case and Cæsarean section in another. It would, he thought, be of interest to know why the three operations were performed in the order they were.

DR. TWEEDY said, in reply, he performed symphysiotomy first because the diameter of the pelvis permitted it and the woman was in labour; pubiotomy secondly because it was the easier operation; and Cæsarean section on the last occasion because the patient was not actually in labour, and he was not certain that the second pubiotomy would have been a safe procedure. With regard to the sterilisation, this was the first case in which he had sterilised.

TUBAL PREGNANCY.

MR. R. D. PUREFOY read a paper on "A Case of Tubal Pregnancy with severe symptoms without rupture," and also showed specimens.

DR. GIBBON FITZGIBBON said that at a first glance on removing a tumour of the sort, one would be justified

in suggesting tubal pregnancy, but in the face of the microscopic report it was difficult to be satisfied. He did not know whether there was anything in the case to suggest that the tube had discharged the pregnancy and the hæmatoma had formed then in the tube.

DR. ROWLETTE said that his examination of the specimen, as far as proving tubal pregnancy was concerned, was negative. On the other hand he did not know that the absence of anatomical evidence was a disproof. The specimen showed a concentrated effusion of blood as if the bleeding were at a definite point. He thought the diagnosis must rest on the history rather than on the examination of the specimen.

DR. TWEEDY said he thought the President in his interesting paper had exhausted the subject of hæmorrhage of the tube. He (Dr. Purefoy) had shown that hæmorrhage could arise without tubal pregnancy. He thought this fact was often forgotten.

MR. R. D. PUREFOY, in replying, said that when the patient came to him her account and the account of the case sent by the physician, together with the physical signs, led him to conclude that it was a case of ruptured tubal pregnancy, and he was surprised to find that the tube was not twisted or ruptured. He could not, therefore, accept the theory of torsion being the cause of the hæmatosalpinx.

STERILITY AND TUBERCULAR PERITONITIS.

DR. TWEEDY read a paper on "Sterility, the salient feature in General Tubercular Peritonitis," which we hope to publish in full in an early number.

SIR WILLIAM SMYLY said that the paper called attention to several points of considerable practical importance. The first was that sterility not infrequently depended upon conditions which could not be diagnosed by palpation alone, and could only be detected after the abdomen had been opened. Therefore, in cases in which it was considered advisable to operate for the cure of backward displacements of the uterus in sterile women a method in which the abdominal cavity had to be opened would be preferable to one in which it had not. The next point raised in this paper was whether one would be justified in going even further and recommending an abdominal operation in a patient who, excepting sterility, had no symptoms whatever. Under certain conditions he agreed with the author of the paper that one should do so.

DR. SOLOMONS said that the question of sterility appeared to him a very difficult one so far as treatment was concerned. According to statistics collected by Brickner and published in *Surgery, Gynecology and Obstetrics*, November, 1911, the operation of posterior division of the cervix only gave a 27 per cent. cure of sterility. If curettage and posterior division had failed to cure sterility, and there were no pathological conditions palpable, he asked should one persist in subjecting a woman to laparotomy for further diagnosis without first ascertaining whether the male was the cause?

DR. GIBBON FITZGIBBON said that in one case in his experience with retroversion of the uterus the only symptom was sterility. He could not make out anything wrong, but on doing a laparotomy he found both tubes diseased in the entire length, and he decided to remove them. He thought that in a number of cases the cause of sterility was in the tubes in the form of disease or occlusion.

THE CHAIRMAN said that a good deal had been heard about displaced uterus and the fixing of same in a correct position, and it appeared to him that all the methods had advantages and disadvantages. Failure, he considered, was bound to follow if the round ligament was shortened and pregnancy afterwards took place. The same observation applied if the thin supports obtained failed to be of use in subsequent pregnancy. The paper opened up a question as to the different methods of draining the abdomen; theoretically he considered the vagina should be the correct method. The use of moist sponges and care in using them was of importance, as the less the intestines were handled the better for the patient. He hoped to hear Dr. Tweedy dealing with secondary sterility on some future occasion.

DR. TWEEDY, in replying, said before any serious operation was undertaken he considered the sterility or

otherwise of the male should be ascertained. He thought that anyone would be encouraged to open the abdomen in a case of one child sterility. He considered the suggestion of insufflation of the tubes an excellent one.

THE NEW LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD THURSDAY, NOVEMBER 14TH, 1912.

The President, DR. P. S. ABRAHAM, in the Chair.

DR. AGNES SAVILL showed a single woman, *æt.* 35, with an eruption on both forearms consisting of round and oval patches of erythema, of about four months' duration, accompanied by some burning sensation but no itching. There was no infiltration nor scaling. The general health was good.

DR. ALFRED EDDOWES said that the condition reminded him of erythema ab igne, and he thought that the arms might have been exposed to some stimulating agent.

The PRESIDENT suggested the possibility of erythrasma.

DR. R. W. BRIMACOMBE showed (1) a case of lupus erythematosus in a woman of 31, a nurse, the condition affecting the central part of the face. She felt the cold a great deal. There was no history of phthisis.

DR. H. SAMUEL, in discussing the treatment of this affection, thought that the carbonic acid snow would react too much in the acute stages of the disease.

DR. EDDOWES agreed with the previous speaker and thought that morning washing should be prohibited. He recommended the use of calamine lotion only and also extolled the virtues of sour milk.

DR. NORMAN MEACHEN said that the carbonic acid snow was more suitable for the chronic, circumscribed, discoid forms of lupus erythematosus, and that the exposure need rarely exceed 25 to 30 seconds.

DR. BREMNER advocated the use of liquor plumbi on account of its constricting effect upon the vessels.

The PRESIDENT thought that quinine in large doses, 15 grains per diem, was often most beneficial. The best local applications were sodium ethylate or phenocamph.

(2) A boy, of six, with a maculo-erythematous eruption upon the body and limbs of some months' duration. There had been no rise of temperature nor general disturbance.

The case excited a good deal of discussion, some members being of the opinion that the condition was one of psoriasis undergoing involution, while others suggested the possibility of a syphilide or of pityriasis rosea.

DR. MEACHEN showed (1) a young man of 21 with SEVERE ICHTHYOSIS.

The condition was congenital, and the skin was variously affected in different parts of the body. Upon the inner sides of the elbows were to be seen dark-brown, heaped-up plates, arranged in mosaic fashion, while on the extensor aspects of the lower limbs the scaling was more irregular and partook of the character of an hyperkeratosis. The face and scalp presented the characteristic drawn appearance and the hair was somewhat scanty. His health was good, but he was small and poorly developed for his age.

DR. TOM ROBINSON thought that the inunction of the real brown cod liver oil was efficacious in such cases.

DR. D. VINRACE suggested the use of liquid paraffin locally, being a very limpid oil, neutral and odourless.

(2) A case of lupus erythematosus in a woman of 56, of fifteen years' duration. Both sides of the face and several areas in the scalp were involved, and a patch on the left side presented some superficial ulceration, probably of traumatic origin. Another small shallow ulcer on the inner side of the right knee suggested the possibility of co-existent specific disease.

(3) A man, of 38, with severe acne over the trunk of long standing. All the lesions had left deeply-pitted scars. He had been operated upon twice for fistula in ano, and had suffered from polyuria, but there was no

glycosuria. The question was, therefore, whether the disease should be called acne necrotica or acne cachecticorum.

DR. WALSH showed (1) a man with a psoriatic condition on the leg associated with well-marked aortic obstruction.

(2) A girl, of seven, with a congenital pigmented hairy mole on the left cheek, immediately beneath which was some slight scarring of a navoid character. On the opposite cheek and upon the chin were other small navoid areas, suggestive of symmetry.

DR. ROBINSON was of the opinion that these cases were really instances of reversion to some primitive type.

He next exhibited a case of lupus erythematosus in a married woman, aged 23, in whom the lesions had made their appearance during the last six months upon the face. There was no history of tuberculosis. The peripheral circulation was poor.

Paris, Nov. 23rd, 1912.

FRACTURE OF THE SKULL.

FRACTURE of the skull without external wound is not always easy to recognise. Functional symptoms alone furnish the basis of diagnosis, facial paralysis, when it exists, and frequently, says Professor Mauclair, a simple ecchymosis of the conjunctiva, the issue of blood, or serosity from the nose or ear, will put one on the track.

In doubtful cases, the lumbar puncture will give important information on the composition, the tension, the colour of the cephalo-raquidian liquid which completes the diagnosis.

In the absence of grave signs, such as coma and depression of the skull, there exist a small number of signs which have their importance. The complications usually observed are: commotion, contusion, and cerebral compression.

Cerebral commotion can exist alone or accompanied by fracture of the skull, and may be classed under three heads: slight, moderate, or grave.

In its slight form, commotion produces a transitory loss of consciousness; the patient, from a blow or a fall, experiences a sense of dizziness, noises in the ears, and appears as stunned. The face turns suddenly pale, the pulse is slow and irregular, and at the end of a few minutes the patient comes back to himself, but unconscious of what has happened to him.

In moderate cases, the phenomena are more pronounced: coma is more profound, muscular resolution and insensibility more complete, respiration is weaker, the pulse soft, compressible and slow; besides, there is incontinence of the sphincters.

This form lasts a few hours, and the patient comes slowly back to life.

In grave cases, resolution and insensibility are complete; the patient succumbs to syncope, cardiac, or respiratory of bulbar origin, after a few days.

The diagnosis of cerebral commotion due to fracture of the skull should not be affirmed before other affections giving rise to coma are considered.

The coma of drink is easily recognised by the special odour of the breath; that of epilepsy by the froth at the mouth, the convulsive form of the attack, and the traces of biting of the tongue.

Cerebral hæmorrhage is generally accompanied by immediate hemiplegia; besides, in apoplexy the face is purple, contrary to what is observed in cerebral commotion, where the face is pale, the coma is more complete, as well as the loss of sensibility.

In simple meningitis, the patient is in a state of torpor and somnolence, rather than coma.

Coma of uræmia is accompanied by convulsions, delirium, hypothermia, and Cheyne Stokes respiration; that of diabetes is characterised chiefly by hypothermia and chloroform breath.

Where the traumatism has been more intense, the brain is the subject of more or less attrition characterising cerebral contusion. At the beginning the symptoms may be confounded with those of commotion. When the contusion is seated over one of the motor and sensorial zones, the cortical lesion will provoke such symptoms as aphasia, facial paralysis.

Ordinarily, these centres are irritated, producing partial contraction of the limbs, the muscles of the face, convulsions, local paralysis. Later on, all these symptoms recede, and the patient recovers, or, on the contrary, complications set in, and notably meningo-encephalitis.

Depression of a fragment of the bone or pressure from blood effusion are the essential causes of traumatic cerebral compression.

The symptoms differ according to the seat of the compression. Intellectual disturbances, particularly aphasia, follow compression of the anterior lobe; that of the middle lobe is characterised by hemiplegia, while where the posterior lobe is compressed anæsthesia is complete.

The general signs of cerebral compression are intense and immediate: slow pulse, stertorous respiration, Jacksonian epilepsy, delirium and coma.

When the compression is due to effusion of the blood, rupture of the middle meningeal artery is generally the cause; the blood is accumulated between the dura mater and the bone, forming a large pancake clot. The symptoms are: loss of sentiment, hemiplegia, total and complete, stertorous respiration, lowering of the temperature, of the pulse, dilatation of the pupil on the side of the compression.

The prognosis of closed fractures of the skull is very grave, on account of the divers possible complications mentioned, of which the most to be feared is meningo-encephalitis, which appears towards the sixth or eighth day after the accident.

GERMANY.

Berlin, Nov. 23rd, 1912.

At the Medical Society Hr. Friedmann brought forward his

TREATMENT OF TUBERCULOSIS

by what must at present be called a secret method. As the treatment and its results have been rather fully discussed in the lay papers I may as well pass on to the discussion that took place after the delivery of the address.

Hr. Erich Müller reported a short series of cases, mostly of surgical disease, in which the treatment under discussion had been very successful.

Hr. Karfunkel was able to report on 450 cases of his own that had been treated by the Friedmann method. They could be divided into the following groups:—Commencing pulmonary phthisis, phthisis of a progressive character, very advanced phthisis, glandular tuberculosis, scrofulous exanthems, scrofulous affections of the eye, tuberculosis of the bones and joints, lupus and cutaneous tubercle. The results were surprisingly alike. In more than 200 cases of pulmonary phthisis he did not see a single case that did not respond in the most favourable manner to the remedy. After the results he had met with he would not think of treating any case of tuberculosis in any other way than by Friedmann's remedy. Twenty-two cases of scrofulous disease of the eye were all healed in a few weeks, four of them having been under treatment for years. He had never seen any relapses. He would also mention that Hr. Friedmann had had the goodness to treat his (the speaker's) own son, æt. 6, who had from his second year been subject to feverish attacks of bronchitis, with a cough like whooping-cough, and coming on every six or seven weeks, so that a suspicion arose as to whether there was not tuberculosis of the bronchial glands. The cutaneous reaction was positive. In connection with the injection an attack came on which lasted four days; but after this there was no return, and the patient had since thriven splendidly.

Hr. Küster said that he had followed Friedmann's treatment for two years. As he had previously said, when we were able to inject living non-poisonous

tubercle bacilli, we should then inject the uninjured protective body into the system, and a great result must follow. He had therefore sent his patients to Friedmann in the fullest confidence, and his confidence had not been misplaced. He had made the observation that if there was a small secreting wound, the results were not so great as he had at first thought them to be. Since Friedmann had, however, adopted the double method of injection—the "simultaneous" method, injecting into both muscle and vein—he had seen the results in Karfunkel's klinik, and he could tell them that he had been completely surprised. He did not think such results had been possible. He was of opinion, however, that great as these results were, those from inoculation would be of greater importance still to Germany. If it was a great thing to cure tuberculosis, it was a still greater to prevent it. Friedmann had compared inoculation for tuberculosis with vaccination for small-pox, which, in well-vaccinated countries, had well nigh disappeared. He had himself seen plenty of small-pox, but many young doctors had never seen a case. Friedmann's inoculation was superior to Jenner's, great as that was, as with the latter there was no reaction. Of course, there would be deniers and objectors, as in the case of vaccination, but science would triumph over them.

Hr. Heymann could but say that he had been surprised and satisfied in the highest degree with what he had seen of the success of Friedmann's treatment. The experiences with his own cases had not been so exclusively good; but it must be borne in mind that, with one exception, they belonged to the worst classes that could be met with in the polykliniks of a large city.

Hr. Blaschko said he could not report such dazzling results as the previous speaker. Hr. Friedmann had said that some failures were due to a too sensitive skin; this acted in such a way that abscesses developed after injection. His own experiences were of a date before Friedmann had begun the double simultaneous injections, and with nearly all his cases abscesses followed, and very little influence was observed on the disease, and especially was this the case when a weeping track was left. In one case of lupus in the axilla, Friedmann made the injection near to the diseased part, and a remarkable improvement followed; but the same patient had also lupus on the ear, and that part did not participate in the improvement, so that Hr. Friedmann had to inject direct into that part also. It would appear, therefore, that tuberculosis of the skin presented far greater difficulties in regard to the treatment than would appear to be present, judging from the reports. He saw a good result in the case of a ward sister who had suffered from a tuberculous infection of the fingers for seven years. She had been treated by himself and others in every thinkable way, but the disease steadily advanced. He sent the patient to Hr. Friedmann, and a few days ago she was brought to him to show herself. He must say that the result had been very good. He would not say yet that a perfect cure had been effected—the time was too short for that; but there had been seven fistulæ, and they were all closed but one. He must say that in that case a quite surprising effect had been produced in an extraordinarily severe morbid process.

Hr. Citron said that useful as dead bacilli were as regarded diagnosis, they were useless in respect of treatment. For treatment and for prophylaxis, if we would obtain good results, nothing but living, unchanged bacilli came under consideration. All the great results of inquiry into immunity, such as Jenner's and Pasteur's had achieved, had been obtained with a living virus, not with Wright's vaccine, which contained dead bacteria material.

He therefore was of opinion that Hr. Friedmann had been on the right path. Although he must recognise this on theoretical grounds so long as he was ignorant of the remedy he must maintain a certain reserve as to practical application.

The greatest inquirer into immunity of the past, Pasteur, had in his time at last met with a mischance with fowl cholera. He started with great success, but met with a check. In many cases his inoculations led to a devastating epidemic. The reason was that his

avirulent material for some reason became virulent. So long as we did not know the nature of the virulence we could not be master of it at will, but some day the tables might be turned and an avirulent virus might for some unknown reason become virulent—so long we should dread the possible change becoming an actuality when treating human beings. With his earlier studies Hr. Friedmann spoke only of a living avirulent bacteria material of a tuberculous nature. If he had succeeded in treating human tubercle bacilli into avirulent material, he should hesitate before advising the use of the virus.

Hr. Orth (Chairman): If Hr. Friedmann's address had not been as complete as it might have been, he (the chairman) was responsible. He had requested Hr. Friedmann to be as brief as possible. He must also acknowledge that the experiments on guinea-pigs which had been made had not given absolutely good results by any means. The animals that had been inoculated by Friedmann's material had certainly lived longer than the control animals, but they had all become tuberculous.

Hr. Klemperer had ascertained years ago that when an animal was slightly infected, so that the disease ran a slow course, and when whilst still ill it was re-injected by a weakened culture, recovery took place. There was here a general rule—a subsequent active immunisation can only act curatively so long as the infection ran a slow course and the immunisation was sufficiently powerful. But they had no immunising material against tubercle, and he might add they never would reach the result of curing tuberculous animals by tuberculin. Dr. Robert Koch had said to him a non-virulent virus must be found for the human subject which could be injected living into the patient, and which would remain alive in him, without causing suppuration. In 1906 and 1907 he had worked with Friedmann with the tortoise bacillus, but they had to give it up on account of the suppuration it caused. The problem now was: Had Hr. Friedmann taken from his bacilli the tendency to set up abscesses? If he had injected them subcutaneously or into the muscles, and they had retained their vitality, without setting up abscesses, he had no doubt of his success. The whole secret of Friedmann's remedy for him was: How had he deprived his bacteria of the power of causing abscesses?

Hr. Goldscheider wanted to know more definitely about recoveries. He wanted to know the exact condition before treatment and the physical condition after it; not that patients got violently hungry or that their condition was much improved. Then, as regarded prophylaxis, he would underline what had been said by Hr. Citron; he must be abundantly satisfied as to the harmlessness of the bacilli before he would inject an army of children with it. He was convinced that the public would be astonished if the Medical Society did not at least set up a note of interrogation in regard to prophylactic inoculation.

AUSTRIA.

Vienna, Nov. 23rd, 1912.

CHEMISTRY OF CANCER.

At the Gesellschaft der Aerzte, Freund said that he had again to seek the indulgence of the members on a subject that he and Kaminer had brought before them some time ago. On that occasion it was shown that when the serum of an uncancerous person was injected into the site of a removed cancer the cancerous cells were destroyed, but if the serum of another cancerous person was injected into a similar site the cancerous cells were not destroyed. The same condition existed when injected subcutaneously. Under these conditions he felt in doubt whether he had removed the cancer or not after a local operation of the total extirpation of the cancerous mass. He thought no radical cure had been effected in the body when this general disposition existed in the serum. To prove its efficacy in another way he had gone further to examine the cancerous mass itself. A piece of tissue was taken from the body and broken up in a 0.5 per cent. solution of common salt and an extract prepared which was applied for 24 hours at a temperature of 40° Cent. to the cancerous cells. The extract from the healthy patient or non-cancerous person showed the same

destructive power on the cancerous cells, while the non-cancerous cell was preserved. The extract from the cancerous patient had the same preservative property of the cancerous cell as the serum had, and exercised a deleterious effect on the normal healthy cell. We may therefore conclude that the cancerous preservative property is the same body as acted in the blood serum. Those extracts were taken from the healthy parts of the cancerous patient. Now, if the extract from a cancerous ulcer of the leg be taken from the margin of the sore it has the same destructive action on the cancerous cell, but if the extract be made from the centre of the sore this solvent condition of the cancerous cell is lost. The same condition exists in cancerous ulcers of the stomach and chronic inflammatory affections of the mucous membrane of the uterus. It must be noted, however, that every cancerous patient has not this loss of power in the central part of the cancer, and even some cancerous patients had in the non-affected or healthy tissue of the body sometimes a solvent power of the cancerous cells, at other times it was absent and existed more frequently in the epithelium cells. We must therefore conclude that the predilection for cancer in a healthy organism is to be found in the normal solution of the tissues and where this is reduced we have now what is termed "Locus minoris resistentiæ." To produce cancer, however, a general disposition is necessary with a pathological condition of the nucleo-globulin in the serum. The presence of a pathological nucleo-globulin is not sufficient of itself to develop cancer if the normal protection of the body is reduced.

UNITED STATES OF AMERICA.

New York, Nov. 14th, 1912.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA.

The third annual meeting was held in New York City this week. This meeting was noteworthy for many reasons. In numbers it surpassed any Congress of a like nature held on this continent, and there can have been few anywhere which have excelled it in this respect. In the neighbourhood of 2,700 surgeons from all parts of America, with a few from Europe, registered. The meeting was unique in that no Congress has ever assembled in which so great attention was paid to

THE CLINICAL FEATURES.

On every day of the week in which it took place, commencing on Monday, November 11th, clinics were held in almost every hospital and sanatorium of Greater New York, and it has been stated that no fewer than 200 clinics took place on each day. New York City is undoubtedly a great surgical centre, and her foremost men in every branch of surgery demonstrated their ability. This is not to say that spectacular or out-of-the-way operations were performed, although many wonderful surgical methods were practised, but as a rule the ordinary routine of the hospitals was proceeded with. To eulogise the value of this mode of arranging a Congress would be superfluous, for it goes without saying that to the general practitioner who does not live in a great city more is to be learned in this way than by the reading of numerous papers. However, the work at the clinics will be dealt with later, and in this account a brief *résumé* will be given of some of the happenings at the stated meetings. A feature which distinguished this Congress was the marked enthusiasm displayed by those who attended. The Waldorf Astoria Hotel was the headquarters of the Congress, and no place could have been chosen better adapted for the holding of such a meeting. Its position is central, and its capacity appears to be almost unlimited. So far as the reading of papers was concerned, the meetings for this purpose were held, with the exception of one, in the splendid ball-room of the hotel on the evenings of the first five days of the week. This room will probably seat, with its boxes and galleries, more than 2,500 persons, and on each evening it seemed to be filled to its utmost capacity. Indeed, at the opening meeting it was uncomfortably crowded, many being unable to obtain seats.

The meeting was opened by Dr. George E. Brewer, of New York City, who, in a short, pertinent speech, introduced the President, Dr. Ochsner, of Chicago. Dr. Ochsner said, in part, that the large attendance at the Congress was an inspiration. New York had always been a surgical centre, but never more so than at the present moment. There was a time when wealth, victory in combat, or personal aggrandisement, was the measure of man's greatness, but now personal service was the prime element of achievement. About half a century ago teachers grasped this fact and impressed upon their pupils that education must include ethical development. A willingness to render service was more profitable to him who received than to him who gave. Dr. Ochsner then went on to point out the significance and value of such a meeting to the visitors, and especially to the younger men, and concluded by introducing his successor to the presidency, Dr. Edward Martin, of Philadelphia, who had done more than anyone to develop and advance the Congress.

Dr. Martin, after introducing the visiting delegates, including Dr. Otrifd Froester, of Breslau, Germany, Mr. Arbuthnot Lane, of London, England, and Dr. J. B. Murphy, of Chicago, and others, delivered his presidential address, the topic of which was "The Treatment of Hepatic Cirrhosis." Dr. Alonzo Taylor, of Philadelphia, read a paper on the "Relations of the Bio-chemical Functions of the Liver to Surgery of the Liver"; after which Dr. William J. Mayo, of Rochester, Minnesota, read a very instructive and valuable paper dealing with the

SURGERY OF THE SPLEEN.

He said we had acquired a fairly exact knowledge of the functions of the organs contained in the abdomen, with the exception of the liver and spleen. The liver was essential to life, one of its chief functions being to receive the products of gastro-intestinal absorption and change them into tissue-building material. The spleen was not essential to life. It performed for the general circulation a function somewhat analogous to the digestive organs—namely, removing from the circulation broken-down blood corpuscles and other material of probable nutritive value, which was sent as part of the portal circulation to the liver for further elaboration. It was also concerned in the metabolism of iron. The spleen was an organ of internal secretion controlled by chemical stimulation through the blood stream. Evidently the internal secretion of the spleen was not important, since splenectomy did not produce serious results, the associated organ taking up the function. Dr. Mayo further defined the functions of the spleen so far as they are known, and went on to say that with the present insufficient methods of diagnosis diseased spleen was not often mapped out until its size was made manifest on palpation beyond the free borders of the ribs. Dr. Mayo discussed leucæmic spleen, and said as it was but part of a general condition, splenectomy would be unavailing. Splenic anæmia was probably a definite entity, and at St. Mary's Hospital, Rochester, they had removed the spleen in eighteen cases of splenic anæmia with most gratifying results.

The speaker next considered conservative splenic enlargements due to malaria, syphilis, typhoid, and tuberculosis, and stated that in a few cases of tuberculosis, when the infection was apparently primary and limited to the spleen, the spleen had been removed with the cure of the patient. Sarcoma was the type of primary malignant disease of the spleen and was rare. Some pathologists held that these were sarcoma and others that they were a type of hyperplasia. As a rule, disease of the spleen was far advanced before a diagnosis was made, and usually the entire organ was involved, making splenectomy the only rational procedure. Dr. Mayo described the *technique* of the operation as performed at St. Mary's Hospital, and said that in their 27 cases there had been two operative deaths.

(To be continued.)

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

EDINBURGH.

MEDICAL TREATMENT OF SCHOOL CHILDREN.

AN important special case on this subject was heard in the Court of Session. A Glasgow ratepayer has raised an action for declarator and interdict against the Glasgow School Board, on the question whether the latter are entitled to provide dental treatment for two school children whose parents, on account of poverty, are unable to do so. The Board proposed to pay for the treatment out of the school fund, and the pursuer denies that they are legally entitled to do so. For the Board, counsel quoted Section 4 of the Education (Scotland) Act, 1908, which is as follows:—"A School Board may, and when required by the Department shall, provide for the medical examination and supervision of the pupils attending schools within their district to such an extent and subject to such requirements as may from time to time be prescribed by any code or minute of the Department, and for the purposes of this section, the school board may supply medical officers or nurses or arrange with voluntary agencies for the supply of nurses and providing appliances or other requisites." Lord Mackenzie asked: "If the statute meant treatment, why didn't it say so?" Counsel submitted that what the statute meant was to provide such medical supervision as would enable children to take full advantage of the education given. The Lord President asked whether counsel asserted that a Board was entitled to spend public money on anything calculated to put a child in a proper state of health? "Are you arguing that, when you find a child in a one-roomed house which is dirty, you are entitled to provide the parents with a two-roomed house which is clean out of the school rate?" Counsel replied that the Board had power to deal with children who were starved or verminous, and practically take these children into their own hands to improve their condition. The Lord President pointed out that every child had a certain amount of dentistry to go through, and that this was a large order. If counsel's argument were right, the health of every child in the school area might be taken in hand. Lord Mackenzie: "This is a very important question; and do you say it all depends on the interpretation of the ambiguous word 'treatment' by a Court of Law whether you are entitled to do all this?" Counsel replied that, in the view of the education authorities, there was no doubt about it; if they were not right, the power merely results in the accumulation of statistics, and does not enable the Board to do anything more for the children. Lord Kinross: "If the power is so extensive as you say, it would have been only to be expected that Parliament should have said so in plain words." Counsel: "I am afraid I cannot say they are absolutely plain words." The view of the School Board was that the matter was within their own discretion. After hearing counsel for the pursuer, the Court made *avizandum*.

EXTENSION OF THE VICTORIA HOSPITAL AND DISPENSARY, EDINBURGH.

The new dispensary buildings were inaugurated on November 23rd, by Lord Dunedin, who performed the formal opening ceremony. Sir Malcolm Morris, London, took part in the proceedings, and described the inception of the campaign against tuberculosis in this country. Letters of apology for absence were read by a number of medical men, including Professor Beraneck, Neuchâtel, who paid a tribute to Dr. Philip's work in connection with the systematic eradication of tuberculosis. A congratulatory cablegram from Dr. Herman Bigg, New York, was also read. There was a large assemblage of those interested in the Victoria Hospital, and the meeting was presided over by Sir Alexander Christison, chairman of the committee. In the course of their remarks Lord Dunedin, Sir Malcolm Morris, and others took occasion to express the hope that an arrangement might be come to between the Insurance Commissioners and the authorities of the Victoria Hospital whereby the latter

agency might be made use of in connection with sanatorium benefit. The new dispensary, which is much larger and more commodious than the existing one in Lauriston, consists of St. Cuthbert's United Free Church and Hall, situated at the corner of Spittal Street and Lady Lawson Street, which have been acquired for the purpose. They are planted in the heart of one of the most populous districts in Edinburgh. The buildings, as altered, include an administrative and educational department. The patients' entrance leads into a vestibule and office, from which there is access to the waiting hall in the nave of the church. The aisles have been divided up to form a series of consulting rooms, dressing rooms, drug laboratories, lavatories, etc. On each side there are four rooms, three *en suite*, constituting consulting room and dressing room for male and female patients. Off each consulting room is a small dark room for laryngoscopic examinations. A separate ante-room, apart from the general waiting room, is provided for patients who attend merely to obtain medicines. The gallery of the church has been converted into research laboratories and an X-ray department, which are fitted up in the most approved fashion. Another part of the gallery has been made into a library, designed to offer to students and practitioners a consulting collection of books on all matters pertaining to tuberculosis. A separate entrance is provided for the use of the medical staff. Adjoining this is the board room, pathological museum, statistical department, and a large lecture hall. There is a large basement, which can readily be adapted to the purposes of increased laboratory accommodation. The cost of the work is estimated at £8,326, and the architects are Messrs. Sydney Mitchell and Wilson.

GLASGOW.

THE FUNCTIONS OF FEVER HOSPITALS.

DR. ALEXANDER JOHNSTON delivered a lecture on Friday last, November 22nd, in Glasgow University in connection with the Glasgow School of Social Study and Training, and took as his subject "The Functions of Fever Hospitals." Dr. Johnston is superintendent at Belvidere Fever and Smallpox Hospital, and in his discourse traced the advance of the modern fever hospital as being the result of the unhealthy conditions under which the people dwelt during the nineteenth century. The introduction of Loch Katrine water supply into Glasgow coinciding with the disappearance of cholera, and the relative preponderance of cases of fever over smallpox, was pointed out as having been influenced by the consequence of vaccination tending to diminish the incidence of smallpox amongst the younger members of the population. The year 1862 was a memorable year for Glasgow, for in it the Sanitary Committee, with the late Mr. Ure as chairman, was nominated, and also by the appointment of the late Dr. (afterwards Sir William T.) Gairdner to the Chair of Medicine in the University, and Professor Gairdner was soon afterwards appointed first medical officer of health, with five assistants, who were district police surgeons. Professor Gairdner undertook work as enormous as it was varied, and the control of fever and the question of hospital accommodation came prominently forward for consideration. For the purpose of isolating and treating cases of fever a hospital was erected in the neighbourhood of St. Rollox containing 136 beds, and the prevalence of fever and its devastating effects was so great that no other infectious disease, apart from cholera and smallpox, which were at that time comparatively scarce, was admitted to the hospital, and which was accurately named a fever hospital. The advantage of isolating infectious disease was shown to have a marked bearing upon the distribution of infection, and the success of the first municipal hospital, opened in the year 1865, was so marked that the estate of Belvidere was shortly afterwards purchased for the purpose of increasing the means or checking and controlling fever.

The fevers having been subdued, and cases of smallpox provided for by the erection of a small-pox hos-

pital, attention was turned to the more destructible infectious diseases of childhood. A resolution was adopted by the Town Council in 1881 to admit all citizens free to the hospitals, and thus the popularity and usefulness of the hospitals was increased. As the fevers had steadily declined, the hospitals were able to devote wards to the treatment of other infectious diseases; and the fever hospitals, as they were originally called, became changed into hospitals for the treatment of infectious diseases.

Besides the benefit to the public health from the removal of sources of infection from the midst of the people, and the isolation in hospitals, the patients suffering from infectious diseases had received the best medical attention and nursing procurable. The relief which the general hospitals obtained from the removal of infectious cases from their wards acted beneficially on the patients for other than infectious diseases, and it allowed these institutions to develop and expand their methods for dealing more particularly with important surgical cases.

The fever hospitals had also become important centres for the training of medical students in the diagnosis and treatment of infectious diseases. Isolation and treatment in hospital had greatly reduced the deaths from infectious diseases, and this reduction had had a material influence in lowering the death-rate of the city from all causes.

QUEEN MARGARET COLLEGE STUDENTS' UNION.

On Saturday afternoon, November 16th, the formal opening of the new union at Ann Street was held, when Miss Elizabeth Thomson, M.A., President of the Union, presided and gave a sketch of the progress of the Union, the house at Buckingham Terrace and the new premises. Queen Margaret students have actually been in possession of their new premises since the early part of the year, and it was thought desirable that there should be a formal opening, to which the students could invite some of the friends who had assisted them in realising their desire to possess premises convenient to the University, which would be sufficiently large for the members attending and in every way adapted for their purpose, with dining-room, drawing-room, library, and other rooms. Lady Stirling-Maxwell expressed her pleasure in being invited to declare the Union open and congratulated the students on possession of such premises.

STIRLING ROYAL INFIRMARY.

The annual meeting of the subscribers was held on Monday, Nov. 18th; Provost Bayne occupied the chair. The directors' annual report was adopted and stated that the work of erecting the additional wards had made considerable progress, and it was hoped that they would be completed in the beginning of next year. The cost of the wards was £12,000, of which already £11,000 had been subscribed.

During the year the number of in-patients treated at the institution had been 509, as against 441 last year, while the out-patients, numbering 2,130, attended at the dispensary, being an increase of 128 compared with last year.

The Convalescent Home at Chartershall had received 186 patients, an increase of 17 on the previous year. The ordinary income for the maintenance of the Infirmary fell short of last year by £69 2s. 1d., and amounted to £1,559 7s. 5d., and the expenditure amounted to £1,952 7s. 7d., an increase of £298 12s. 4d. more than last year, the total deficiency on the year's working being £393 0s. 2d.

APPOINTMENT.

DR. JOHN A. WATT, M.B., D.P.H., has been appointed Tuberculosis Officer and Assistant County Medical officer for Derbyshire. Dr. Watt is a distinguished Graduate of Aberdeen University, and for many years practised in Aberdeen, in which city he held many public medical appointments, and, at the present time, is Senior Assistant County Medical officer of Health for Lanarkshire.

BELFAST.

THE INSURANCE ACT.

THE Derry County Council met last week to consider a model scheme submitted by Dr. Charles

Dickson, one of the medical inspectors of the National Health Insurance Commissioners, for dealing with tuberculosis in the county. Mr. Barrie, M.P., said that he would be entirely in favour of the scheme if they had full information about the grant in aid from the Treasury. But they were asked to enter on large and unknown expenditure on sanatoria, dispensaries, tuberculosis doctors, local doctors, nurses, attendants, and so on, relying on the Treasury's assurance that they would give some help. He thought that they should wait three months till the Treasury's assurance took some more definite shape. He reminded them of how their local taxation accounts had worked out; they had gone to large expenditure, relying upon a similar promise, but the fund became insolvent, and in County Derry alone they had suffered a loss of £7,900. He moved the adjournment of the matter till their January meeting. This was seconded and passed unanimously.

SANITARY CONDITION OF PORTADOWN.

The latest instance of the prophet having no honour in his own country comes from Portadown, where Dr. Rowlett, the well-known and energetic health officer, condemned an unsanitary area containing 196 houses, and recommended their demolition as unfit for human habitation. Naturally, this caused a fluttering among property owners, and a special inquiry and visitation was carried out by the Sanitary Committee of the Town Council. They have reported that many of the houses are models of cleanliness, well looked after, and filled with healthy families of children! Not more than 10 per cent. of the houses needed repair. Dr. Rowlett tried in vain to persuade the Council that clay floors, absence of ceilings, and proximity of privy middens did not conduce to health, and the report of the Committee was passed.

QUEEN'S UNIVERSITY OF BELFAST.

The report of the Vice-Chancellor of Queen's University for 1911-12 has just been issued, and discloses a flourishing state of affairs in most departments. The new students numbered 177, of whom 65 men and 66 women matriculated, and the remainder were admitted through other recognised avenues, such as the senior grade intermediate examination. The entry shows an increase of 40 on the previous year. The medical school has 266 students, the science school 90, and the arts 159.

THE OFFICERS' TRAINING CORPS, which is doing so much for the University, entered into possession of its new home last week, when a spacious drill hall, with rifle range, offices, etc., was opened by Brigadier-General Count Gleichen, K.C.V.O. The new hall abuts on Botanic Avenue, on the site of the old ball-alley, which past students will well remember. The corps, which is the senior one in Ireland, numbers 180 members, and of these 104 have received the A certificate and 47 the B certificate. There are three companies of infantry and a medical unit, and there is a prospect of forming an army service corps unit as well. Count Gleichen announced that the Civil Service Commissioners, as regarding the medical unit, were considering the advisability of granting commissions in the Army Medical Corps and in the Naval Medical Service to officers of the Officers' Training Corps who had passed this medical training and had a medical certificate. If such an arrangement is made, no doubt it will act as a further inducement to medical students to join the corps. Their teachers will give them every encouragement to do so, as the corps' training is of inestimable benefit in every way, both physically and morally.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE DEFENCE OF AUTOMATISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is evident that "Barrister-at-Law" (*vide* letter *Times*, November 15th) is not in full possession of the facts concerning the remarkable case tried before

Mr. Justice Scrutton at Derby, and referred to in your last issue.

Although medical evidence as to the physical and nervous disabilities of the prisoner was given in detail by the experts who had personally examined him, this evidence was practically ignored by his lordship when charging the jury.

When dealing with the question of the somewhat rare, but nevertheless well recognised mental phenomenon, the mental expert explained in detail and with extreme care that, in his opinion, the personality A, which committed the crime, was not the whole individual, but only an integral part of the fully awake conscious personality, B. He also said he believed, from authentic records and from cases within his own experience, that in such instances the fully awake conscious personality B knew nothing of acts committed automatically or subconsciously by A.

He did not countenance the fiction of "Dr. Jekyll and Mr. Hyde," to which the learned judge had so often referred, although there were many instances on record in which there had existed conditions of alternating personality. Referring to the case under trial the expert described the abnormal condition of the prisoner at the time of the committal of the offence as having been, in his opinion, one that was well recognised in medical practice—namely, "mental automatism" or "fugue," and as being midway between somnambulism and a minor form of epilepsy.

On cross-examination the expert most emphatically denied that in this case the personality A, which committed the crime, was either complete or responsible inasmuch as the condition was purely automatic, and, therefore, irresponsible. Be it noted also that the fictitious division of the personality into personality A and personality B was made by the counsel for the prosecution and adhered to by him throughout and later adopted by the learned judge to illustrate his argument in spite of the protests of the medical expert against any such splitting of personalities, there being but one personality—*i.e.*, the one fully-awake and conscious; any other abnormal mental states occurring in the same individual being not evidences of the existence of another personality, but evidences of somnambulism, mental automatism, fugue, or minor epilepsy, in which conditions all sorts of complex mental and physical activities might be displayed.

When summing up to the jury, Mr. Justice Scrutton said: "In that dock there is sitting a body; in the body is a brain which in some mysterious way controls and regulates the body; and in some way, which Science does not yet understand, there is attached to that brain the power of determining action and the power of judging whether that action is right or wrong. That body, brain and judgment bear the label C, and the prosecution say that that body, brain and judgment, with that label, between June 29th and July 2nd, took away a motor car of Dr. B— with the intention of depriving Dr. B— permanently of the possession of that car. The answer made is that part of that body and brain may have taken the motor car, but the whole of it did not do so; part of it, and the responsible part, was asleep and woke up on July 2nd, and that part and the responsible part never knew anything about and never intended the act, and, therefore, you cannot punish the whole body and brain for what the inferior part did when the governing part was asleep."

To these remarks no exception need be taken, but the subsequent remarks by the learned judge on the merits and demerits of the fictional "Dr. Jekyll and Mr. Hyde," as if this was the case now before the jury, could scarcely be regarded as in keeping with the practice of the law, and more especially so after the refusal of the medical men to deal with the consideration of cases other than those which were authentic in fact.

After a medical expert had stated on oath that he was of opinion that the prisoner was at the time of the committal of the act neither fully-awake nor completely conscious, and that the individual had been but incompletely represented, his Lordship evoked a laugh by remarking, "I take it that it was whatever is in the dock now."

Mr. Justice Scrutton, in the course of his summing up, referred also to the danger of establishing such a precedent in a Court of Law, and harked back to the early Victorian findings with regard to the MacNaughton case. His Lordship also said he had an uncomfortable suspicion that if, instead of there being in the dock a well-dressed body of apparent education charged with stealing a motor car, there had been a poor man in rough corduroys, charged with breaking a window and going off with some jewellery, and that poor body had said, not through learned counsel or specialists, that part of the body did the deed, but the responsible part was asleep, probably the judge, and certainly the jury and everybody in court, would have thought very little of the defence. They must be very careful that they did not make for the rich a law they would not make in the case of the poor.

The questions put to the jury were:—

(1) Did the prisoner on June 20th to July 2nd take away Dr. B—'s motor car with the intent to permanently deprive him of possession of the car?

As there was no denial as to the commission of the act the jury rightly answered "Yes."

(2) If so, was he *insane* at the time he did it? Inasmuch as the plea of insanity formed no part of the defence—the mental expert having emphatically declined to agree to the suggestion made by the counsel for the prosecution that the prisoner was insane any more than a somnambulist or epileptic was necessarily insane—the question in itself had absolutely no bearing whatsoever upon the case under consideration.

This case serves but to emphasise the absurdity of attempting to harmonise early Victorian Law with modern medicine, and it would seem advisable in the interests of justice that such cases should be tried in the light of existing knowledge.

I am, Sir, yours truly,
London, November 25th, 1912. MEDICUS.

REVIEWS OF BOOKS.

MEDICAL DIAGNOSIS. (a)

DR. MITCHELL STEVENS modestly declares that it is with much hesitation he puts this result of many years' work before the public. It is true that there has been more than a sufficiency of books on diagnosis within the last few years, and the physician is inclined to be indifferent when he sees another announced. Too many of these books are merely ill-digested compilations through which the reader wades, conscious at every turn that the work is impersonal, and that the author has no convictions or opinions, and is without the critical faculties necessary to make a compilation of any use. Dr. Stevens' book is, however, of quite another class. It is the expression of the wide personal experience of a highly observant and critical physician. As such it cannot fail to be of service to an intelligent reader, be he hospital physician, general practitioner, or medical student.

Dr. Stevens in the first instance, after a brief introduction on case-taking, devotes a section of seventy-five pages to general symptoms and general physical signs. The entire of this section is deserving of close reading. The later sections dealing for the most part with special groups of diseases will doubtless be of service rather for reference than for consecutive reading. We cannot, however, imagine a better preparation for a clinical lecture, both for teacher and student than the perusal of the paragraphs or chapters dealing with the particular subject of the lecture.

We find little in Dr. Stevens' teaching to criticise. Many, however, will think him too dogmatic in saying that in some cases of undoubted typhoid fever no Widal reaction can be obtained. Such cases are generally found, on further investigation, to be cases not of typhoid, but of para-typhoid infection of one or other variety. We are surprised, indeed, not to be able to find any reference to para-typhoid infections.

Dr. Stevens' book is well turned out, and furnished

(a) "Medical Diagnosis." By W. Mitchell Stevens, M.D., M.R.C.P. Demy 8vo., pp. xi. and 1,571, with 177 illustrations. London: H. K. Lewis. Price 25s. net.

with both a good index and a full table of contents, features whose importance in a book of the kind cannot be exaggerated.

ROYAL LONDON OPHTHALMIC HOSPITAL REPORTS.

THE third part of the Royal London Ophthalmic Hospital Reports for this year (a) is by no means meat for babes; it contains nine papers which for their solidity and thoroughness remind one of the contents of a German medical magazine much more than the usual English ones. The most important of these papers is a really masterly monograph on Primary Tumours of the Optic Nerve, by Mr. A. C. Hudson, the Curator of the Hospital Museum. It runs to 123 pages, and includes notes of 191 cases, gathered from all parts of the world. Of these the great majority, 118, were of a type met with chiefly in quite young people, of slow and painless growth, which Mr. Hudson looks on as essentially an overgrowth of glial tissue. There is no local recurrence after removal of these tumours. Most of the other cases were either fibrous or endothelial tumours of the nerve sheath.

Mr. J. H. Parsons contributes two papers, one on Scotopia, or Vision in Dull Illumination, and a second, highly mathematical, on the Perception of a Luminous Point. Mr. G. Coats has three papers on pathological subjects.

LITERARY NOTES.

THE Calendar of the National University of Ireland for 1912 (Dublin: Alex. Thom and Co.) has recently reached us. It is a handy volume, bound in neat dark green cloth. It prints in full not only the Charter of the University, but the Irish Universities Act (1908), documents it is useful to have at hand. The lists of officers, both of the University and of the constituent colleges, are given, as well as the members of the Senate, of Convocation and the graduates of the University.

* * *

WE have received from Messrs. Beynon and Co., the Cheltenham art publishers, a set of advance proofs of Guy's Hospital sketches. The set consists of eight capital etchings of various parts of the buildings, by Hanslip Fletcher, the illustrator of "London, Passed and Passing," and other works. The plates are fine collotype impressions of sketches made by the artist at the hospital last spring, and they catch the spirit of the place in a way that will go straight to the heart of every old Guy's man. The cost of the set is one guinea and a half—a remarkably moderate price for signed proofs of fine quality. The series only requires to be known amongst the many persons interested in Guy's Hospital to command a large and steady sale.

* * *

IN the introduction to the little "Manual for Women's Voluntary Aid Detachments," the author informs us that his object is that of indicating to the members of a Women's Voluntary Aid Detachment what will be the scope of their duties if ever they are called upon to serve in time of war. Although the intention is excellent, and although we are not disposed to question the accuracy of the author's statements, the writer of this note, as an army medical officer of many years' experience, is compelled to point out that most of the information herein conveyed is what any woman gifted with common sense would certainly know for herself, and a good deal more can only be learned by practical training and experience. On this ground, therefore, it cannot be said that the book accomplishes any distinctly useful purpose.

* * *

IN "The Valley of Vision" (Simpkin, Marshall and Co., 1911), Dr. G. M. Irvine has made a curious and interesting contribution to psychological literature. His book is a series of half-a-dozen visions or

(a) "The Royal London Ophthalmic Hospital Reports." Vol. XVIII., part III. London: J. and A. Churchill, July, 1912.

adventures, which we take to be the dreams of a patient suffering from the delirium of acute disease. A word overheard by the subject gives in each case the starting-point, and the various series of events which follow are developed with much skill and ingenuity. Some of the tales are the exercise of mere fancy, but in others Dr. Irvine satirises various phases of modern life. The politicians of his own Ulster, the members of his profession, modern financiers, and controversial theologians—all are treated with a severe, though humorous, pen. It is unfortunate that the book has been disfigured by "sixteen full-page, sepia plate drawings."

MEDICAL NEWS IN BRIEF.

The Treatment of Tuberculosis in Edinburgh.

THE new dispensary of the Royal Victoria Hospital for Consumption in Lady Lawson Street, Edinburgh, was opened last week by Lord Dunedin. Sir Alexander Christison presided. Lord Dunedin said that one of the first men who really woke up to the fact that tuberculosis could be combated by an organised campaign was Dr. Philip, of Edinburgh.

Sir Malcolm Morris, one of the founders of the National Association for the Prevention of Consumption, said that but for the work carried on by Dr. Philip and the laymen who had co-operated with him tuberculosis would never have been dreamt of as suitable for inclusion in the Insurance Act. The Chancellor of the Exchequer would never have dared to touch tuberculosis if it had not been for the movement carried on in Edinburgh.

A demonstration of the methods of the Edinburgh system for the prevention and treatment of tuberculosis was given in the United Free Assembly Hall in the evening.

University College, London, and the New Laboratories.

THE new Pharmacology Laboratories at University College built by the generosity of Mr. Andrew Carnegie, will be opened by the President of the Royal College of Physicians of London, Sir Thomas Barlow, Bart., K.C.V.O., M.D., F.R.S., on Wednesday, December 4th, at 5 p.m. The Right Hon. Lord Reay, K.T., The Chairman of the College Committee, will preside, and the Vice-Chancellor of the University of London, Dr. W. P. Herringham, has promised to be present.

The Institutional Treatment of Inebriety in Scotland.

THE report of the Inspector for Scotland under the Inebriates Acts issued last week states that at the end of 1911 there were seven institutions open for the treatment of inebriates, and during the year the receptions at reformatories totalled 166, as against 143 in the preceding year; whilst the number of patients entering retreats was 140, as against 129 in 1910.

The Inspector (Mr. James C. Dunlop) says the figures point to the conclusion that in Scotland the institutional treatment of the voluntary patient is becoming more frequently taken advantage of, and at present there was no indication of greater numbers being compulsorily detained in the reformatories. At the end of 1911 there were 44 retreat patients, 31 certified reformatory inmates, and 19 State reformatory inmates.

Staffordshire Memorial to King Edward.

LORD DARTMOUTH opened last week a new wing of the Wolverhampton and South Staffordshire General Hospital, erected by the townspeople at a cost of £8,000 as a memorial to King Edward. It forms the first section of a reconstruction scheme, the estimated cost of which is £60,000. Mr. William Smith, a working man, handed to Lord Dartmouth a cheque for £1,000 raised by working men of the town and district.

Medical Sickness and Accident Society.

At the usual monthly meeting of the Executive Committee of this Society, the claim account presented showed a decided margin in favour of the Society as against the amount expended. Quite a new feature of the Society's experience is to be met with

in the number of motor accidents. These show a steady increase, and some at any rate have been serious and have involved long periods of incapacity. It is important to note that no extra premium is charged to members using motor cars or motor cycles. Under one of the present Bonus schemes should death take place before sixty-five their representatives would be entitled to an amount which increases automatically with the length of membership and the sum insured. It was decided to hold the annual meeting at an earlier date than usual. Full details of this will be given by advertisement in the medical journals some months in advance.

University of London.

THE following have passed the third (M.B., B.S.) examination for medical degrees:—

Honours.—C. M. Jones (*a*), Westminster; C. J. Marshall (*a, b, c*, University Medal), Charing Cross; J. Taylor (*a*), Univ. Coll. (*a*) Distinguished in medicine; (*b*) distinguished in pathology; (*c*) distinguished in forensic medicine.

Pass.—C. Aldis, Guy's; W. M. Ash, London; C. A. Birts, Univ. Coll.; F. H. Bousfield, London (R. F. H.) Sch. for Women; R. Brewitt-Taylor, St. Bartholomew's; B. W. Brown, Westminster; B. I. Cohen, St. George's; T. P. Cole, Guy's; Gertrude Dearnley, London Sch. for Women; L. A. Dingley, Univ. Coll.; H. T. Evans, St. George's; W. B. Foley, St. Thomas's; J. M. Foord, Univ. of Leeds; G. E. Genge-Andrews and W. S. George, Guy's; A. J. Gibson, St. Bartholomew's; C. Gibson, London; C. D'O. Grange, St. Bartholomew's; F. W. Hamilton, Middlesex; A. W. Hansell, Univ. Leeds and Univ. Coll. Hosp.; A. W. Havard, London; B. W. Howell, St. Bartholomew's; A. H. Hudson, St. Thomas's; G. W. B. James, St. Mary's; Mary S. Jevons, London Sch. for Women; Mirza Mohammed Khan, J. S. H. Lewis and R. H. Liscombe, Univ. Coll. Hosp.; Dorotay C. Logan, Univ. Coll., Cardiff and Lond. Sch. for Women; Emily C. Macirone, London Sch. for Women; P. J. Monaghan, Guy's; J. F. O'Connell, St. Mary's; H. W. Parrott, London; Purushottam Tulidas Patel, Bombay and London Hosp.; Sara L. Penny, London Sch. for Women; F. H. Rees, Univ. Coll.; J. F. G. Richards, Guy's; W. G. Rogers, U. C., Cardiff, Charing Cross and London; E. G. Saunders, St. Thomas's; W. F. V. Simpson, London; H. K. V. Soltau, St. Bartholomew's; J. L. Stewart, Guy's; J. Tattersall, St. Mary's; F. R. Todd, St. Bartholomew's; E. A. Wilson, Middlesex.

F. C. McCombie, M.D., King's Coll. Hosp., has passed the B.S. examination for students who graduated in medicine in or before May, 1904.

Apothecaries' Hall of Ireland.

NOTICE OF ELECTIONS OF EXAMINERS FOR 1913.—The annual election of Examiners (Courts A and B) will be held on Friday, December 20th, 1912, at 4.30 o'clock p.m. All applications to be forwarded to the Registrar, 40 Mary Street, on or before Tuesday, December 17th.

Results of Quarterly Examinations.—Intermediate Examination.—Passed in Anatomy—Ambrose Macaulay, Francis Duckworth, Daniel Crowley. Passed in Physiology and Histology—Frederick Duckworth, Daniel Crowley. Passed in Materia Medica—John B. Barry, Morgan B. Kennedy. Completed Examination—Frederick Duckworth, John B. Barry, Morgan B. Kennedy.

Final Examination.—Passed in Medicine—James B. Barry, S. Ram Rao, Frederick Duckworth. Passed in Surgery—Andrew S. Dillon, S. Ram Rao. Passed in Medical Jurisprudence and Hygiene—John B. Barry, Frederick Duckworth. Passed in Pharmacy—Frederick Duckworth. Completed Examination—S. Ram Rao, Andrew S. Dillon. Examination for Registered Medical Practitioner—Thomas P. Magnier, M.B., B.Ch., B.A.O., N.U.I.

Society of Apothecaries of London.

THE following candidates, having passed the necessary examinations, have been awarded the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery and Midwifery:—T. J. Gibson and W. C. Himely.

SUMMARY OF RECENT MEDICAL LITERATURE ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Coliform Organisms in Healthy and Infected Urinary Tracts of the Female, with Report on Vaccines.—Williams and others (*Jnl. Obs. and Gyn. Brit. Emp.*, xxii., 2), in the first instance, tested the urine taken from thirty women about to undergo operation, and again twenty-four hours after operation. The bacilli isolated gave the characters of the *B. coli* group. Forty-two per cent. of the cases before operation, and 92 per cent. after operation were found to contain organisms. At the early examinations the colonies were relatively few, at the second examination they were unduly overcrowded, whether the patient had been catheterised before or not. No symptoms attributable to the presence of the bacilli or their increase in number were evident. To overcome the objection of contamination in taking the specimens, twelve other specimens were taken by puncture of the bladder during laparotomy in patients under operation for uncomplicated displacements. Four of the specimens gave on culture a similar Gram-negative motile bacillus. Although the cultural characters of the bacilli were identical, the serum relation, as shown by agglutination, was widely different. In twelve cases of chronic or acute pyuria *B. coli* was pathogenic in four, probably a contributory cause in two, incidental in two, and in four not found. The biological relation between organisms culturally identical is slight, and the cultural relations of organisms associated with pyuria show pronounced variations. For this reason there is little hope that good results can be obtained by the use of stock vaccines. As regards the treatment of bacilluria with pyæmia, the authors consider the cure is represented not by the total absence of organisms from the urine, but by the disappearance of the ordinary evidence of inflammation. Frequent examination of the urine is necessary for treatment, and routine administration of the same dose of vaccine is not likely to produce the best results. In administering the auto-vaccines the authors aim at producing a moderate local reaction. In acute cases small doses—5 to 10 million—are sufficient to produce this, but if no local or general reaction occurs the dose is cautiously increased till it appears. No acute case should be given an initial dose of more than 10 million, and even three million will produce effect on the temperature. Any exacerbation of the symptoms is an indication that the maximum therapeutic dose has been given. The opsonic index is of use for dosage, but the authors have chiefly judged by the clinical condition. In acute cases it must be remembered that the auto-inoculation of the patient is proceeding in addition to the artificial inoculations, and therefore at times an overdose is unintentionally given. The results in acute cases were excellent. The doses were increased up to 200 million in the more persistent cases at increasing intervals. The acute symptoms subside rapidly, but some pyuria is apt to persist. In subacute and chronic cases the initial doses were from 50 to 100 million, and increased to 200 and 500 million, the intervals being also greater.

F.

Primary and End Results of Radical Abdominal Operations for Cancer of the Uterus.—(*Surg., Gyn., and Obs.*, xv., 2).—Three papers dealing with this subject are published, the first by R. Peterson, who reports 17 cases and says he adheres to the operation, because all others have given uniformly bad ultimate results. Fundal cases are much more responsive to treatment than cervical disease, but they should be subjected to as thorough an operation. There was a primary mortality of 10.5 per cent. It was 42.8 per cent. in the first 14 cases; this he considers was due to the prolongation of the operation, which is a potent cause

of shock. Excessive fat is considered a contra-indication. Dissection of the glands should only be done after a short operation, when the patient is in good condition; the wide removal of the parametrium is of more importance, and the ultimate results do not justify an increase of the primary mortality. Peritonitis is best avoided by rendering the vagina clean before operation and shutting it off by right-angled clamps. Infection is favoured by drainage, which should be restricted and shut off from the peritoneal cavity; but of 14 cases operated on five years ago or further back five are living and free from recurrence. The second paper, by H. C. Taylor, reports 28 cases. He says that in those cases in which the ordinary abdominal or vaginal hysterectomy is done, 50 per cent. have had symptoms lasting less than three months, while only 10 per cent. had symptoms for more than six months. Of the cases of radical operation only 18 per cent. had symptoms under three months, while 40 per cent. had them for six months or longer. Statistics from Germany show that 54 per cent. had symptoms less than three months, and only 18 per cent. for over six months. This accounts for the better results obtained by the operation in Germany, and the chief need is for the better education of the medical profession and public in the early recognition of symptoms. He does not consider right-angle clamps necessary, but thinks equally good results can be obtained by thoroughly wiping out the vagina when first opened. The operation is justifiable in cases with bad prospect of permanent cure, by reason of the great relief of pain. He has verified no case over five years still alive. The third paper, by F. T. Taussig, deals with 60 cases. He reports five cases well at the end of five years out of 14 operated upon, and eight cases well after four years out of 25 operated upon. He considers that in very advanced cases the immediate operation risk and the likelihood of recurrence such that these patients are best classified as inoperable. He divides his cases into four groups—(1) those diagnosed by microscopic evidence 3, all possibly saved by operation; (2) cervix alone macroscopically involved, 16 cases, 14 possibly saved, 2 died from operation; (3) cervix and vagina involved and slightly extended into parametrium, 26 cases, 10 possibly saved, 6 died from operation; (4) extensive involvement of parametrium, but not hopelessly inoperable, 15, none possibly saved, 10 died from operation. F.

Potassium Iodide in Bier's Treatment.—Bier (*Medical Review*, October, 1912), in order to avoid the formation of cold abscess, and in open tubercular lesion of luxuriant granulations, which sometimes follow prolonged passive congestion, advised the limitation of treatment to one or two hours daily. This reduces the number of complications, but largely robs the treatment of its value. Lately, Bier, recognising the value of the old observation that iodine acts not on the germs of syphilis, but on the proliferating tissues it provokes, was led to try the internal administration of iodides to prevent the excessive granulation tissue formation arising in the course of treatment by passive hyperæmia. He reports several cases where the combined treatment was most successful. He gives 45 grains of potassium iodide daily to adults, and proportionate doses to children. The congestion can then be maintained for four hours thrice daily, and can be pushed till considerable hyperæmia and œdema have been induced, provided pain and discomfort are avoided. Iodides alone have little or no action on tuberculous granulation tissue, and treatment by passive congestion alone is at first as beneficial as when iodides supplement it. But without the administration of iodides, the treatment of severe articular

tuberculosis for twelve hours daily with passive congestion usually leads to the formation of cold abscess. By preventing this complication, iodides enable passive congestion to exert its beneficial action undisturbed and uninterrupted. Though the mode of action of iodine on the tissues under certain conditions may not be clear, its prevention of the familiar complications following passive congestion is a fact. S.

The Suturing of Tendons.—Kerr (*Practitioner*, November, 1912) confines himself to the consideration of incised wounds received about the forearm, wrist and hand. As asepsis is so important in these cases, the "first aid" treatment should be confined to the application of sterilised lint, covered by ample sterilised cotton wool. Digital pressure on bleeding points is not permissible. The diagnosis of the injury should be made by examining the action of the tendons before the first dressing is removed. To facilitate this a tight bandage is applied over cotton wool around the wrist and the tourniquet removed. Exposure of the wound, painting of the part with iodine, the placing of two fingers above to control the arteries, is followed at once by the application of "mosquito" artery-forceps to the bleeding vessels. The tendons most commonly divided are the palmaris longus and the flexor carpi radialis, and frequently the flexor longus pollicis. As the tendons are usually stretched and prominent at the time of the accident, the median nerve lying free from tension is more out of harm's way, usually the distal end of the lesion only is seen, but sometimes this end is hidden unless the hand is placed in the extreme flexed position. The risks of sequelæ of sepsis are much greater if the flexor sublimis or deeper tendons are divided. Local anaesthesia by the "block" method is all that is generally required. Only reliable catgut is used. The divided ends of the tendons are sought for by appropriate manoeuvres, as, for example, if the flexor of the middle finger is cut, possibly its upper end may be brought into view by hyperextending the ring and index fingers. If this fails, dissection will be required, but the fasciæ cut must again be united separately and carefully when the tendons have been united. After-treatment consists in immobilising the cut tendons completely from 14 to 21 days during the formation and consolidation of the granulation tissue which constitutes the uniting material. Functional treatment must commence during the third week, while adjustment of length is still possible in the young connective tissue, which after six weeks practically cannot be further lengthened. S.

Antityphoid Inoculation.—Spooner (*Jour. Amer. Med. Assoc.*, October 12th, 1912) records the results of three years' experience of antityphoid inoculation in the training schools for nurses in Massachusetts. In order to produce immunity, Spooner used small doses frequently repeated of a low virulence vaccine. The stock culture from which the vaccine was prepared had been isolated from the spleen of a patient with enteric fever in 1902, and consequently its attenuation has been considerable. Four injections were given in each case at intervals of five days, the dose varying from one million to six million, according to the body-weight of the patient. It was found that given in this way the vaccine caused slight inconvenience, and seemed to produce a protection among the nurses, a class which had previously been found to be eight times more liable to the disease than the average individual. The case mortality among the uninoculated was found to be nearly nine times greater than among the inoculated under similar conditions. Furthermore, no permanent untoward effects have been recorded from over 5,000 injections. Examination of the blood of the inoculated patients showed a certain protection lasting for at least two and a half years. The use of this method of protection has been shown to be safe in two epidemics and very efficient in at least one of them. K.

Death after Salvarsan.—Ruhe (*Cleveland Med. Jour.*, September, 1912) records the results of a very careful histological examination of several of the organs of a

patient who died five days after the injection of 0.5 gram of salvarsan given intravenously for the treatment of syphilis. Complete anuria for four days followed the injection. On the fifth day after the injection about three ounces of clear urine were passed. At the autopsy evidences of severe intoxication were found, the main effects of which were seen in the liver and kidneys. These organs showed degenerative changes and proliferation of the parenchymatous elements. These histological changes in the liver and kidneys were similar to those that are produced in experimental arsenic poisoning. K.

Bismuth Poisoning.—Warfield (*Amer. Jour. of the Med. Sciences*, November, 1912) records an interesting case in which symptoms of chronic bismuth poisoning followed the injection of about two ounces of bismuth subnitrate paste into an ilio-psoas abscess. The patient was a poorly developed child of nine years of age, who had been under treatment some time for spinal caries. Subsequent to this injection the child displayed typical symptoms of chronic bismuth poisoning, with ulceration of the mouth and the black line on the gum margin. Warfield states that there are reports of more than twenty deaths caused by the administration of bismuth preparations internally, or as dressings for large raw wounds, particularly burns. It would appear that one should be very careful that the paste, if injected into sinuses, is afterwards extruded or removed. The internal use of bismuth for X-ray work in the intestines is not devoid of danger where inflammatory conditions exist or where the patient is much run down in health. Bismuth salts, like lead and mercury salts, may cause definite and characteristic symptoms of poisoning in more or less susceptible persons. "Peculiarly characteristic of bismuth stomatitis is the whitish, diphtheritic membrane which caps the ulcers." The visceral lesions caused by bismuth also show that it is one of the metallic poisons, and therefore should be used with caution. K.

Chloroform Poisoning.—MacCardie (*Birmingham Med. Review*, October 15th, 1912) records several cases in which toxic symptoms developed in patients after the administration of chloroform for the production of surgical anaesthesia, and apparently due to the use of the drug. As a result of his investigations in this subject he draws the following conclusions:—(1) Never administer chloroform if etherisation is possible even to children or pregnant women. (2) Avoid carbohydrate starvation, or any other form of starvation before operation. (3) If chloroform must be used, administer dextrin or bicarbonate of soda freely for days beforehand, especially if the patient be young or his condition septic. (4) If post-chloroform poisoning develops, administer freely soluble carbohydrates (dextrose) and bicarbonate of soda, in the worst cases injecting the dextrose into the subcutaneous tissues and rectum, or even intravenously.' K.

NEW APPLIANCES.

ENDOLYTIC TUBES.

WE have received from the Endolytic Tube Co., Hampton-on-Thames, a series of the new endolytic tubes for clinical diagnosis, and after testing the same we have no hesitation in saying that the introduction of these ingenious contrivances marks a revolution in the art of urine testing. Test tubes, bottles of solution and the spirit-lamp are all rendered unnecessary, for the practitioner, armed with a set of the tubes, can rely upon the speedy and accurate determination of the abnormal constituents of urine literally by the bedside. The test solutions are enclosed within special capillary tubes, which are simply broken across and brought into contact with a drop or two of urine. We consider the method cleanly and reliable, and that the inventors' claim of "bringing the full advantages of the laboratory to the bedside in the waistcoat pocket," are fully justified. A box of 100 Endolytic Tubes in a compact nickel case, holding 15 to 20 tests, is sold at 5s.

NOTICES TO CORRESPONDENTS, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION.—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

MR. W. I. (London, W.) is thanked for his paper which is marked for early insertion.

M. B. (Perth).—The best Japanese oil of peppermint is produced in Okayama and Hiroshima Prefectures, and it is remarkable for the large proportion of menthol crystals it contains. It is chiefly grown on the hillsides, and it is said that attempts to introduce the American and English plants, which yield an oil superior in taste and odour to the native plants, have not been successful.

THE USE OF CELLULOSE.

THE Departmental Committee appointed by the Home Secretary to inquire into the precautions necessary in the use of celluloid have opened their inquiry, and will be glad to receive evidence on the following heads:—

(1) The inflammability of celluloid, its liability to explosion and spontaneous ignition; standard tests for ascertaining purity and inflammability; the cost, reliability and practical utility of non-inflammable substitutes.

(2) Serious accidents due to fire or explosion in this country or abroad in factories or workshops or retail shops, or in connection with storage, conveyance, or private use.

(3) Government and local regulations existing or proposed.

(4) The various uses of celluloid in manufacture; the precautions adopted and their adequacy.

(5) The dangers of celluloid; how far they are realised by the public.

It is not the intention of the committee to limit witnesses to the above, but they think it desirable to give some indication of the kind of evidence which appears likely to prove useful for the purpose of the inquiry.

Persons desirous of giving evidence or of submitting information to the committee are requested to communicate with the Secretary, Mr. C. G. Markbreiter, of the Home Office.

DR. F. R. C. (Somerset).—It would be premature, in the absence of more specific information, to pronounce definitely as to the value of Dr. Friedmann's discovery. It is stated in the lay Press that over one thousand patients have been treated with his anti-tuberculous preparation, and that it is perfectly innocuous. Such statements must necessarily, be accepted with some reserve until further medical details are forthcoming.

ERRATUM.—"Phtisis—a New Remedy."—In the interesting letter by Dr. J. W. Lane in our issue of November 20th, an error occurs in the direction, "add to each ounce of solution when used cocaine *Hg.* gr. 1/4th." It should have been—cocaine hydrochlor. gr. 1/4th to each drachm.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 27TH.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.), —8.30 p.m.: Council Meeting; 9 p.m.: Dr. W. M. Ettles: Special Lecture—Demonstration of Diseases of the Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics:—2 p.m.: Throat Operations (Mr. Gillies). 2.30 p.m.: Children's Out-patient (Dr. T. R. Whiphram); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Dunstan). 5.30 p.m.: Eye Operations (Mr. Brooks).

BROMPTON HOSPITAL FOR CONSUMPTION.—4.30 p.m.: Lecture by Dr. Fenton: Demonstration of Cases.

THURSDAY, NOVEMBER 28TH.

CHILD STUDY SOCIETY, LONDON (Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.).—7.30 p.m.: Discussion on the Outlook of the Adolescent towards Livelihood (opened by Mr. A. H. Paterson and Mrs. M. O'Brien Harris, D.Sc.).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynecological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture: Mr. E. Gillespie: Tuberculous Bone and Joint Lesions, their Diagnosis and Treatment.

Appointments.

FOX, W. T. B., M.B., M.S. Edin., Certifying Surgeon under the Factory and Workshop Acts for the Blyth District of the county of Northumberland.

GREER, M., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Acts for the Corris District of the county of Merioneth.

JACKSON, D. J., M.D., B.Ch., R.U.I., Second Assistant Medical Officer at the Mental Hospital, Whitechurch, Cardiff.

JEFFREY, GEORGE R., M.D. Glasg., F.R.C.P. Edin., Physician-Superintendent to the Bootham Park Private Mental Hospital, York.

LEE, D. CHISHOLM, M.B. Edin., Assistant Medical Officer at the Warneford Mental Hospital, Oxford.

LLOYD, BERTRAM ARTHUR, M.B., B.S. Lond., F.R.C.S. Eng., Resident Medical Officer at Charing Cross Hospital.

LONG, H. B., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Acts for the Bicester District of the county of Oxford.

Bacancies.

Ayr District Asylum.—Junior Assistant Physician Salary £140 per annum, with board, lodging, and laundry. Applications to Dr. McRae, Glengall House, Ayr.

Crichton Royal Institution, Dumfries.—Second Assistant Physician. Salary £200 a year, with apartments, board, and laundry. Applications to the Physician Superintendent.

Joint Counties Asylum, Carmarthen.—Second Assistant Medical Officer. Salary £160 per annum, with board, lodging, washing, etc. Applications to the Medical Superintendent.

Guy's Hospital.—Gordon Lecturer on Pathology. Salary £600 per annum. Applications to the Treasurer, Superintendent's Office, Guy's Hospital.

Lincoln County Hospital.—Junior House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Secretary-Superintendent.

Lowestoft Hospital.—House Surgeon. Salary £100 per annum, with board, residence and laundry. Applications to E. S. Norton, Clerk, 148 London Road, Lowestoft.

Leicestershire and Rutland Asylum.—Junior Assistant Medical Officer. Salary £150 per annum, with board, residence, and laundry. Applications to W. J. Freer, Esq., Clerk to the Visitors, 10 New Street, Leicester.

Wakefield General Hospital.—Second House Surgeon. Salary £100 per annum, with board, lodgings, and washing. Applications to the Hon. Secretary, Clayton Hospital, Wakefield.

Dublin Joint Hospital Board.—Consulting and Visiting Physician to Sanatorium, Crookings. Salary £100 per annum. Applications to T. O. Fitzgerald, Secretary. (See advt.)

Apothecaries Hall of Ireland.—Election of Examiners. Applications to the Registrar. (See advt.)

Incorporated Dental Hospital of Ireland.—One House Surgeon, one Prosthetic House Surgeon, four Instructors in Conservative Dentistry. Immediate application to W. A. Shea, J.P., D.L., Registrar. (See advt.)

Births.

GAUNTLETT.—On Nov. 17th, at Bloxham, Oxon, the wife of Harry Leon Gauntlett, M.R.C.S., L.R.O.P., A.K.C., of a daughter.

HUTCHINSON.—On Nov. 18th, at 22 Queen Anne Street, W., to Dr. and Mrs. Robert Hutchinson, a son.

SMALLEY.—On Nov. 17th, at Suva, Fiji Islands, the wife of James Thornton Smalley, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

WALKER.—On Aug. 4th, at Naini-Tal, U.P., India, the wife of Major J. N. Walker, I.M.S., of a son.

Marriages.

GARDINER-HARE.—On Nov. 19th, at St. George's, Hanover Square, Harold Gardiner, M.B., B.S., only son of F. A. Gardiner, Esq., F.L.S., of "Inversnaid," West Heath Avenue, N.W., to Constance Mabel, only daughter of Henry T. Hare, Esq., F.R.I.B.A., and Mrs. Hare, of 31, Cumberland Terrace, Regent's Park.

JOHNSTON-CRAIG.—On Nov. 19th, at All Saints', Knightsbridge London, H. M. Johnston, M.D., of Stranorlar, Co. Donegal, to Amy Cordella, widow of Dr. James Craig, Leicester, and youngest daughter of the late Dr. Snoad, 286 Aylestone Road, Leicester.

MCCALL-BROWN.—On Nov. 19th, at the Burgh Halls, Maxwell Park, Glasgow, Alexander Bowle McCall, M.D., to Ellen (Nettie), daughter of the late T. G. Brown, of Glasgow.

Deaths.

CHILDS.—On Nov. 23rd, at Torquay, Annie, the wife of Christopher Childs, M.D., of Boscar, Looc, Cornwall, and daughter of the late J. W. Macrae, Esq., aged 61.

ELLIS.—On Nov. 23rd, at Monkendons, Maidenhead, aged 20, Phyllis Edythe, dearly beloved wife of Carlton Atkinson Ellis, F.R.C.S.E., after a long and painful illness.

PESKETT.—On Nov. 22nd, at Simla, Halland, Sussex, from pneumonia, Arthur William Chalmers Peskett, M.A., M.B., B.C. Cantab., son of the late Surgeon-Major William Peskett, Indian Army.

SPARKE.—On Nov. 22nd, at West Hill, Mansfield, Notts, George Whitefield Sparke, M.R.C.S., L.R.C.P., late Asst.-Surgeon Royal Artillery, youngest son of the late John Guyse Sparke, M.D., R.M., in the 84th year of his age.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX."

VOL. CXLV.

WEDNESDAY, DECEMBER 4, 1912.

No. 23.

NOTES AND COMMENTS.

At Aberdeen last Friday, Mr. Lloyd George entered a vigorous defence of his Insurance Act. He pointed out with vehement force the advantages of his scheme as follows:—
"Consumption fought with the whole strength of a great Empire, disease combatted in the lowliest homes, children fed whilst their fathers are fighting death! The first man amongst my foes who has carried a plan through which will assuage such human misery as that, let him cast the first stone." We trust that the Chancellor of the Exchequer does not count the medical profession amongst his enemies, although he himself has certainly forced them into a position of sharp defensive criticism. Medical men will not reject the principles of a measure that makes for the national health, which is the very polestar and inspiration of modern medical science. Mr. Lloyd George has provided a paltry six millions for medical benefits—the price of three ironclads—and a part only of that sum is set aside for medical men. The pay he offers is paltry in return for professional services of a highly skilled and responsible kind. Does the Chancellor realise that the whole of the mighty task of rendering medical aid to the poor of the nation has hitherto been discharged by medical men either gratuitously or at a mean recompense tendered under degrading conditions? Now the State has assumed the burden of responsibility, and on terms that are still scandalously inadequate, seeks to allot compulsorily to other shoulders that portion which deals with medical administration. Why should medical men be the agents of Mr. Lloyd George's vicarious philanthropy? That question the MEDICAL PRESS AND CIRCULAR has been asking, in season and out of season, since his Insurance legislation first saw the light of day.

A LARGE audience awaited Professor Metchnikoff last Friday at the Royal Society of Medicine. He discoursed in lucid and polished style upon man's warfare against tuberculosis. It was interesting to hear from this veteran of science an account of his first grim struggle with the disease. At twenty-three years of age he married a lady of the same age, who suffered from consumption. He tended her closely for four years—until she died—but did not contract the disease. This immunity he attributes to the fact that he had in his childhood been inoculated with the infection in a mild form. "Unconscious inoculation," he said, "by mild or benign strains of the tubercle bacillus is known to occur naturally and to lead to immunity." Some assumption of this kind seems necessary to explain the facts presented to

us on all sides. The learned Professor did not hesitate to push his view to its logical conclusion, for he claimed that the diminution of the death-rate from tuberculosis in London, Hamburg and Copenhagen was probably due to such immunisation. In a fine peroration he expressed a hope that in the not far distant future the great animal *homo sapiens* would triumph over the microscopic plant *bacillus tuberculosis*.

An amusing incident has occurred in connection with sanatorium administration in Ireland. It seems that Sir Charles Cameron, the Medical Officer of Dublin, considered tobacco a useful or necessary adjunct in the treatment of a consumptive patient. He generously offered to pay for the tobacco, but the Committee declined his offer, and the patient was supplied with a small supply of tobacco at the expense of the State. A fortnight later the Insurance Commissioners for Ireland wanted to know from what fund the Committee proposed to repay the cost of that particular item. The reply was to the effect that Sir Charles had ordered the tobacco as a useful drug, which was to be found in the "British Pharmacopœia" under the heading of *Nicotiana Tabacum*. The Insurance Commissioners, after consultation with various eminent lawyers, decided that there was no Statutory authority for the expenditure of money in this particular direction. There the matter stands for the present, but it offers a fine field for future official wrangling. As to tobacco and the Pharmacopœia, it was formerly employed to a limited extent in therapeutics, but it is doubtful whether it is ever so employed at the present day. Still, nothing is impossible to the genius of an Irishman, and we may yet live to see tobacco restored as a useful drug in the treatment of tuberculosis.

THE general recognition of the part played by the house fly in the spread of infectious disease is a boon to the public in many ways. For one thing it opens their eyes to the nature of disease germs and the devious methods by which they are distributed. Many a household has yet to learn that one of the best ways of ridding a room of flies is to expose a small dish of sweetened milk to which a little 40 per cent. formalin solution has been added. The latest plan of attack is highly scientific and promises to be no less deadly. It is that of inoculating flies with a culture of a microscopic fungus which is extremely fatal to those little pests. The discoverer of this agent is Mr. Hesse, a young student at the Working Men's College, Camden Town. His experiments will, of

Mr. Lloyd George as Vicarious Philanthropist.

Tobacco as a Drug.

Metchnikoff on Tubercle Immunisation.

The Deadly House Fly.

course, need corroboration before they can be accepted as scientifically correct, but they are based on lines that contain no inherent improbability.

LEADING ARTICLES.

THE GENERAL MEDICAL COUNCIL.

THE presidential address of the General Medical Council, in the hands of Sir Donald MacAlister, is always of interest to the profession, an important part of the affairs of which are entrusted to the management of that body. On the present occasion it dealt with various matters of importance, although it contained no very new or startling propositions. So far as that goes, indeed, it lacked the hint or promise of coming reforms in the Council which to some extent we had become accustomed to under the presidency of Sir Donald. It has long been recognised by medical men that the method of their internal government is cumbrous, antiquated, and ineffectual so far as many of the objects of self-government are concerned, such as, for instance, the protection of the profession against unqualified practice and the carrying out of necessary reform. The constitution of the Council is of a mediæval character which renders it a sort of close corporation representing the interests of a number of corporate qualifying bodies and Crown nominees, together with a trifling and inadequate direct representation of the medical electorate. To keep such a body in touch with the spirit of modern times this constitution would be reversed, and the bulk of the Council would be elected by the medical practitioners of the United Kingdom. It is a matter of wonder how a powerful body of educated men could have so long tolerated the present condition of affairs, and one may hope that when the battle with the Government over the National Insurance Act has been won the profession will turn its newly discovered powers of collective action towards the reform of the General Medical Council. Why should medical men not have a governing body like that of the Incorporated Law Society, with powers of adjusting fees, of administering internal discipline, of prosecuting illegal practitioners, and of defending and advancing their interests generally? Until the Council is recast as a business body on some such practical lines it must continue to fall lamentably and deplorably short of the duties that legitimately appertain to a body holding so high and prominent a position. In answer to pleas for reform the Council has usually fallen back upon the limitation of its statutory powers, whereby it is entrusted with certain specific duties, such as the regulating of medical education, the enforcing of domestic discipline and the maintenance of the *Register*. The close and peculiar relationship of the General Medical Council to the Privy Council, however, confers upon it absolutely unique powers of influencing medical legislation. As a matter of fact that influence has been thus used during the past few months, namely, to

secure amending legislation. In the course of his remarks Sir Donald MacAlister reported that in response to suggestions from the Council the Lord President has prepared and introduced into the House of Lords a Bill for amending a few particular sections of the Medical Act, 1886. The proposed change is the election of direct representatives every five years, with details adjusted so as to save the money of the Council. Surely this would have been an unrivalled opportunity for increasing the number of the direct representatives, and for introducing other much-needed reforms. As economy was the avowed object of the Bill, and inadequate income its excuse, there would have been an excellent opening for replenishing and sustaining the exchequer of the Council by altering the terms of registration or by other sound financial steps, such as a tax upon the wealthy licensing bodies. If the measure reaches the Commons we trust it may attract the serious attention of legislators on both sides of the House. Most medical men probably think that the disciplinary powers of the Council are already administered with sufficient stringency. It was announced by the President, however, that the Home Office and the police have now undertaken to communicate to the Council the names of all medical men who come within their official cognisance as offenders. The Council would secure the gratitude of the medical profession were they to devote a little of this Draconian rule to the castigation of those who trespass on the field of legitimate medical practice, and by the stress of their illegal competition drive qualified practitioners into questionable and devious paths. In Canada, as announced by the President, amending medical legislation has been obtained. One great outstanding fact is that a single qualification is to be secured for all the Dominion. Another is that the profession is to be represented adequately by direct election. So far as can be gathered from a glance at a summary of the proposed changes there is no adequate penal power conferred against unqualified practice. It may, perhaps, be assumed, however, that a popularly elected council would sooner or later find means of dealing with that most disturbing and pernicious element of social as well as of professional life. With such an example before it our own General Medical Council might be expected to turn some attention to its own defects, such as the one-portal examination; its constitution; and the lack of protection afforded to the fundamental economic interests of medical practitioners. Individually the Council is composed of men of high standing and of unimpeachable honour, but that fact does not compensate for a conservatism of policy and lack of ideals in a body that holds in the hollow of its hands the future progress and welfare of the medical profession.

LUNACY IN LONDON IN 1911.

THE twenty-third annual report of the Asylums Committee of the London County Council for the year 1911-12, made in pursuance of Section 190

of the Lunacy Act, 1890, has just been issued. It contains much that is of interest to the student of social reform or of eugenics. From the statutory returns made by the various clerks to the various London boards of guardians it appears that on January 1st, 1912, the Council was primarily responsible for finding accommodation for 20,429 persons. This year the increase in the total number of London lunatics is greater than was the case on January 1st, 1911, though the average yearly rate of increase is by no means so high as it once was. In dealing with the question of readmissions, the report shows how much difficulty is involved in the duty of discharging patients and how great is the responsibility placed upon those who have to decide whether cases are fit for discharge. It is often hard to decide how far continued detention is justified in the case of an apparently cured lunatic when it is practically certain that on his entry into ordinary life his unstable mental equilibrium will speedily become unbalanced again, or in the case of a feeble-minded person, who is quiet and apparently behaves rationally so long as he is subject to the ordered routine of an institution, but who, once he is outside and exposed to the common temptations and irritations which normal individuals can overcome, will exhibit unmistakable evidence of his deficiency. Appeals from friends and considerations of public expense alike are apt to weigh in favour of discharge. Experience, however, shows that it is not always the wisest course, even on the ground of expense, or the kindest, to discharge. It is clearly to the public interest, so far as the law permits, to keep in detention a feeble-minded person who is a potential nuisance to society and a probable source of further burdens on the rates. The fact seems to be that the majority of the patients in asylums nowadays—whatever may have been the case in former times—are not, in a true sense "curable" cases. There is a large and increasing percentage of cases in which there is an unfavourable prospect of recovery. The sub-committee appointed a year ago to consider and report upon the question of the relation of heredity to lunacy is still pursuing its investigations. The three principal causes that are alleged to have led to the admission of three thousand patients into the ten asylums of the Council are hereditary insanity, mental stress, and alcohol. Epilepsy, physical privation and injury are also responsible for many of the cases. According to the report of Dr. F. W. Mott, F.R.S., the Director of the Pathological Laboratory and Pathologist of the London County Asylums, the scientific work achieved during the year has maintained its usual high standard, many valuable publications having been made upon nervous and mental disease, and it is noteworthy that considerable attention has been paid to the results obtained by the Wassermann reaction in general paralysis of the insane. Recent work has been directed to the comparative

value of the reaction on the blood serum in this disease; the results have shown that a positive reaction can be obtained with the serum in practically the same proportion of cases as with the cerebro-spinal fluid. This also shows that the serum reaction is of great value in the diagnosis of general paralysis, for should a case of suspected general paralysis fail to give the reaction with the blood, the case may for all practical purposes be dismissed as free from this disease, and the patient thereby saved the inconvenience of lumbar puncture for the withdrawal of cerebro-spinal fluid. During the course of this investigation, particular attention has been paid to the details of the *technique*. The original *technique*, as devised by Professor Wassermann, has been followed to the exclusion of all suggested modifications, the majority of which have been found quite unreliable. Experience seems to show that the delicacy of the test depends on the accurate standardisation of the reagents used, especially in the case of the liver extract. It is satisfactory to note that the improvement in the condition of the asylums as regards dysentery has been maintained during the past year. The incidence of tuberculosis does not show much variation from year to year, but the figure, 1.92 per cent., is not large. The value of music, and especially of choral singing, in asylum therapeutics is fully recognised by most, if not all, of the various superintendents. In connection with the all-important question of the prophylaxis of insanity, the Medical Superintendent of Horton Asylum, Dr. John R. Lord, makes the following pertinent remarks with which we conclude:—"Insanity is often a retribution for the sins and lack of wisdom of men and women alike. Syphilis and alcoholic excesses are preventable, and a community which allows of imbeciles, criminals, and degenerates being at large and mating deserves all the punishment it gets. I am one of those who recognise the impracticability of surgical eugenics. I doubt its efficacy without exterminating a large proportion of the human race. A study of heredity shows clearly that the sane members of a neurotic stock are as dangerous to succeeding generations as the insane, while great minds and powerful personalities are often blood relations to social weeds. This is no excuse, however, for inactivity; some of the gross conditions associated with reproduction of the species should be tackled. Sterilisation should be put on the same legal footing as abortion. It is the mating of degenerate with degenerate that does the greatest harm and which occurs so frequently. Imbeciles and feeble-minded persons should be segregated, not only for the good of the race but from pure humanity, to remove them from suffering, poverty and crime. The general public will never sanction too much interference with the liberty of the subject, but two things are practicable and should meet with a large measure of approval. The first is the retention of control of feeble-minded children after the age of sixteen, for life if necessary, and secondly, mea-

asures to prevent men and women entering into the marriage contract without being informed of the existence of previous insanity, hereditary and communicable disease, etc. These should be made the subject of statutory declaration prior to marriage. They could not be made a bar to marriage in the present state of public opinion, but unsuitable and disastrous marriages would often not be undertaken as they are now through sheer ignorance."

CURRENT TOPICS.

Medical Men and the Royal Society.

At the customary anniversary meeting and dinner of the Royal Society on Saturday (St. Andrew's Day) last, an interesting account was given by Sir Rickman Godlee, President of the Royal College of Surgeons of England, of the relations of the Society to medicine. Not a few members of the medical profession enjoy, and have enjoyed, the distinction of Fellowship of the Royal Society, an honour which stamps its possessor as one who has directly contributed to the sum total of scientific knowledge. A considerable proportion of medical men were included among the founders of the Society itself, while among the distinguished men who have occupied the presidential chair, five were members of the profession. The first was the celebrated Sir Hans Sloane, who was president in 1727. The next was Sir John Pringle in 1772, who was the greatest authority on military medicine and hygiene, and published many works on those subjects and some on gaol fever and the plague. Then came Sir Benjamin Brodie, 1858, who, while essentially a surgeon, did some valuable scientific work in physiology and comparative anatomy. Huxley was president from 1883 to 1885, and no one who had ever heard Huxley could forget the flow of perfect English in which he brought forward his entrancing subjects. Finally there was Lord Lister, who was president from 1895 to 1900. By such intellectual giants as these the medical profession has been represented in an official capacity upon the most important scientific body in the world.

The Incidence of Ophthalmia Neonatorum in Scotland.

In 1907 the British Medical Association appointed a committee to investigate and report upon the prevalence and prevention of ophthalmia neonatorum in the United Kingdom. This report was issued in 1909. Among its conclusions was that this affection accounts for upwards of 10 per cent. of all cases of blindness. Dr. Thomas F. Dewar has been engaged in a similar enquiry as regards the chief centres of population in Scotland. In his report, recently presented to the Local Government Board for Scotland, it is concluded that ophthalmia neonatorum is less prevalent than it was 25 or even ten years ago; that actual loss of vision from this cause is less frequent than heretofore all are agreed. Nevertheless, the disease is not so uncommon, nor grave impairment of vision as an effect of it so rare, that it can be regarded lightly or with indifference. It would appear that at the present time about 500 cases occur annually in Scotland, and that of these 30 to 40 suffer some impairment of vision, and 5 to 10 become economically blind. These figures probably understate rather than exaggerate the truth. Dr. Dewar is of the opinion that if the facts regarding the prevalence, preventability, and dire results of ophthalmia neonatorum were brought prominently to the notice of local authorities, further action, based

upon the circumstances and needs of each area, might well be left to the initiative of the local authorities themselves. The general opinion has been expressed that apart from or in addition to, statutory notification of ophthalmia neonatorum, much might be done to restrict its incidence and still more to control its ravages, were a Midwives Act for Scotland (on lines generally resembling the English Act) to be passed by Parliament.

The Little Green Devil.

SINCE the first of October absinthe may no longer be imported into the United States of America. Although we are rather ready to look upon certain types of American legislation as experimental and connected with the scare waves that periodically pass over that continent, yet this time the Solons of the Senate are "making good." If an appreciable quantity of absinthe is introduced into any country, it is high time for the law to step in and crush the insinuating invader before he has time to grip the country in his beautiful green coils. More absinthe is consumed in France than in all the rest of the world, and lay and scientific opinion is seriously perturbed about the effect of this consumption on the manhood of the race; moreover, it was only at the end of the Algerian War that this alluring drink was first introduced. In making absinthe, besides the chief ingredient—wormwood, other essences and extracts are added, some alcoholic and some not, and a *soupeon* of opium caps the savoury mess. Absinthe's chief power for evil lies in the fact that its effects are confined almost solely to the nervous system. First nerves and then brain fall under the spell. A man may have two or three glasses and go about his business free from all effect for hours, and then suddenly he may become irritated, melancholy, seeing visions, and dreaming dreams. Terrifying hallucinations are his lot till he has worked off the effects of the drug, and then he hears again the irresistible call of the little green demon that sits in the glass. At first the drink is taken with the big French slabs of sugar and well diluted, but absinthe makes the heart grow fonder, and your real devotee takes it neat. In these countries absinthe is fortunately left alone. It may be that our lumps of sugar are not adapted for the iridescent dropping that is the absinthe fiend's only æsthetic pleasure, or it may be that our love for other intoxicants is too strong. In this respect as in most things, abstinence is as easy as temperance is difficult.

The Doctor's Car.

THE Olympia Show has turned our fancy to thoughts of motors and such like things. With such a display of all that is latest and best—it were a heresy if in this connection we did not consider the two terms synonymous—in the land of the automobile, we wonder why the more pre-historic types of vehicle are still on the road. The pity is that a super-abundant percentage of these rattle-traps is owned by the medical profession. In country districts the doctor's car is often known by the noise it makes. A man who will have straw laid in the street to protect his patient from the noise of the harmless necessary cart, will not hesitate to drive up to the very door in a car to describe which Virgil might easily have altered his onomatopœic hexameter to—*quadrucrotante putrem sonitu quatit machina campum*. Why the doctor should be satisfied with a shabby noise-machine when four-cylindere ghosts are so cheap it is hard to say. If he would drive his dull car away to the scrap heap, and indulge in one of the silent beauties that are

now so cheap, he would find that his nerves, his practice, and his æsthetic sense would reap benefit. Just at present we fear, however, that few medical men care to lay out the price of a new car, though with the advent of a new type of vehicle, the cycle-car, it is probable that automobilism will become more popular than ever among those who previously demurred on the grounds of expense.

The Medical Profession and the Home Rule Bill.

In his opening address to the General Medical Council the other day, the President, Sir Donald MacAlister, stated that no reply had yet been received from the Government to the resolution of the Council, asking that legislation relating to the Medical and Dentists Acts should, in the Home Rule Bill, be reserved to the Imperial Parliament. In the meantime the Bill is going rapidly through Committee, and no one knows whether the Government has adopted the view of the General Medical Council or not. The matter is of considerable importance, as it would be highly inconvenient to have multiple authorities set up in these countries for the keeping of separate medical registers. We are not, of course, making any suggestion that the standard which might be adopted by one registering authority might vary from that set by another. Separate authorities would, however, lead to manifold inconveniences. The point is, we believe, non-controversial, and we cannot understand why the Government has not adopted the suggestion of the General Medical Council.

The Treatment of Nile Boils.

THE special type of boil known as "Nile Boil," not to be confounded with "Bouton de Nil," a totally different affection, derives its name from the fact that its occurrence usually coincides with the time that the Nile is rising or in flood. An interesting account of the condition is given by Capt. R. G. Archibald, M.B., R.A.M.C. (a) Pathologist and Assistant Bacteriologist to the Wellcome Tropical Research Laboratories, Khartoum, who has had special opportunities for studying it during the last four years. Europeans and natives of Egypt are affected alike, men being attacked more frequently than women. The earliest lesion starts at the base of a hair-follicle as a painful, red spot. Suppuration occurs in two or three days' time, and after incision and separation of the slough the surrounding tissues are seen to be much undermined. Single boils rarely exist, others occurring near the original one or in distant parts of the body. Staphylococci are the cause of Nile boil, mixed infections never having been observed. Fomentations and incisions are only of temporary benefit and do not prevent the condition from recurring. The treatment which has given the best results is vaccine-therapy by means of an autogenous vaccine. 250 million are injected as an initial dose, followed, four days afterwards, by a dose of 500 million and then a weekly injection of 500 million until six doses in all have been administered. By this means it is stated that an assurance can be given of a certain and successful cure.

PERSONAL.

MR. AUSTEN CHAMBERLAIN has received £500 from the British India Steam Navigation Company towards the fund of £100,000 which he is raising for the London School of Tropical Medicine.

(a) *Journal of Vaccine Therapy*, November, 1912.

MR. A. L. CANDLER, M.B., B.S., F.R.C.S., has been appointed Medical Officer to the Exeter Dispensary.

DR. O. A. J. N. MURISSET, of Edinburgh, has been appointed Chief Tuberculosis Officer for Northamptonshire.

COL. H. O. TREVOR, R.A.M.C., has taken up duty as Assistant Director of Medical Services at Headquarters of the Cork District.

DR. C. WILFRED VINING, M.D., B.S.Lond., M.R.C.P.Lond., D.P.H., has been appointed Honorary Physician to the Leeds Public Dispensary.

DR. HUGH MORTON, M.D.Glas., has been appointed Extra Honorary Physician at the Dispensary, Royal Hospital for Sick Children, Glasgow.

DR. H. NEVILLE CROWE, M.B., Ch.B.Birm., L.R.C.P., M.R.C.S., has been appointed Honorary Physician to the Worcester General Infirmary.

DR. JOHN A. WATT, M.B., Ch.B., D.P.H.Aberd., has been appointed Assistant County Medical Officer and Tuberculosis Officer to the Derbyshire County Council.

THE following members of the medical profession have been called to the Bar:—J. M. Acland, M.D., M.R.C.S., L.R.C.P. (Lincoln's Inn); G. C. Hancock, M.R.C.S., L.R.C.P.; O. Hall, L.R.C.P., L.R.C.S. (Middle Temple).

DR. PETER FRASER, who gave up an appointment worth £800 a year some years ago in order that he and his wife might devote themselves to missionary work at Lushai, India, has now returned to this country consequent upon ill-health. He will take up his residence at Hemllan, Denbigh.

DR. R. STENHOUSE WILLIAMS, who has accomplished much valuable work in public health and bacteriology at Liverpool, is about to sever his connection with the University of Liverpool to take up an appointment under the Board of Agriculture, with headquarters at University College, Reading.

THE new pharmacology laboratories at University College, built by the generosity of Mr. Andrew Carnegie, will be opened by the President of the Royal College of Physicians, Sir Thomas Barlow, on Wednesday, December 4th. Lord Reay, Chairman of the College Committee, will preside, and the Vice-Chancellor of the University of London, Dr. W. P. Herringham, has promised to be present.

THE Paul Philip Reitlinger Prize, offered this year for an essay embodying the result of some research work on a medical subject, has been awarded to Frederick James Fitzmaurice Barrington, M.S., University College Hospital Medical School, for an essay on "The Innervation of the Bulbo-urethral Glands, and their Histological Changes during Activity."

THE LORD MAYOR will open the annual conference of the National Association for the Feeble-minded to be held at the Guildhall on December 13th, when the subject for discussion will be "Legislation for the Feeble-minded," and papers will be read on "The Administrative Question" and "The Position of the Feeble-minded under the Government Bill." The chair will be taken by Mr. W. H. Dickinson, M.P.

SURG.-GENERAL CHRISTOPHER PEARSON has been appointed Honorary Physician to the King in the vacancy caused by the death of Inspector-General of Hospitals and Fleets Sir Herbert Mackay Ellis. Dr. Pearson was Surgeon of the *Invincible* during the bombardment of Alexandria, and served throughout the naval phase of the Egyptian war. He joined the Service in 1875, and is the senior man on the active list of the Medical Branch.

A CLINICAL LECTURE

ON

SOME THERAPEUTIC POINTS.

By HERBERT FRENCH, M.A., M.D.Oxon., F.R.C.P.Lond.,

Assistant Physician, Pathologist and Lecturer, Guy's Hospital, London.

THE points that I hope to discuss constitute a continuation of a paper read before the Woolwich Medico-Chirurgical Society at Easter this year, and published in THE MEDICAL PRESS AND CIRCULAR, May 1st, 1912. As on that occasion, so now, I must apologise if the different parts of it seem to you too disjointed. The different therapeutic points that I wish to bring before you have no connection with one another; many of them are far from new, but I think they all merit attention on account of their utility in practice. The first point is:

THE VALUE OF ADRENALIN CHLORIDE APPLIED LOCALLY IN THE TREATMENT OF GRAVES'S DISEASE.

There is probably no malady in which a greater diversity of treatment has been and is adopted by different authorities; in no malady is the probable course of the disease and the ultimate prognosis in any particular case more difficult to assess; in no malady, therefore, is it more difficult to convince one's self and others as to whether the treatment that is adopted is itself really doing good or whether the improvement would not have come about equally well if other measures had been adopted, or even no measures at all. Nowadays I suppose the first thing which has to be decided in one's own mind is whether one should advise Kocher's operative treatment as a routine or not, and every man must formulate his own opinion for himself upon this point. If I were to place myself in the position of a patient suffering from ordinary Graves's disease and my medical man were to advise me to have it treated by removal of part of the gland, I should not be content with his telling me that a great many patients are cured by the operation; I should want him to be able to say that I was almost certainly not one of the kind likely to succumb to the operation itself. Now, so far as I have been able to judge, there are no criteria yet known by which we can say that any particular individual suffering from Graves's disease can certainly be operated upon without the risk of death soon after the operation, apparently from fulminating thyroid poisoning, or something of that kind. This being so, if I were the patient I would rather have other measures than surgical ones tried in the first instance. Amongst those which have done undoubted good in many cases may be mentioned the use of the X-rays locally to the gland; various forms of electrical treatment, particularly the interrupted galvanic current, one pole of the battery being over the thyroid gland region of the front of the neck, the other over the upper dorsal spines posteriorly; and simple treatment by rest in bed and feeding up without the administration of any particular drugs. The great value of rest in bed and a liberal dietary in acute cases is well known, but it is seldom possible to continue the rest in bed until a stage even approaching cure has been reached. As a rule, the rest can be continued until the acute progress of the malady has been arrested, but presently the patient has to be allowed up, notwithstanding the fact that the disease is still present, and then it is that the practitioner in

charge of the case finds the need of resorting to all kinds of remedies and different therapeutic measures in the hope of making the malady retrogress still further. The number of different drugs that have been given internally to patients who have become much better, or even perfectly well, *post hoc*, if not *propter hoc*, is very great; so great indeed, that it seems likely that the drugs themselves were not the cause of the recovery. The use of the milk of thyroidectomised goats, or the oral administration of hypodermic injection of serum from similar animals has proved disappointing in practice. Treatment by the injection of hot paraffin or boiling water into the gland in the hope of causing some of the parenchyma to atrophy as the result of the inflammatory changes so produced has not yet been given a very general trial. I have not space here even to quote all the various other lines of treatment that have been resorted to. I should like to mention one in particular, however, which, though it may not relieve all cases, has certainly seemed to be the direct cause of the improvement in some who have previously resisted a large number of other kinds of non-surgical treatment: and this is by means of the local application of a solution of adrenalin chloride to the neck over the region of the thyroid gland.

My attention was first drawn to it by my friend Fleet-Surgeon Dawe, but I am not sure whether I use the preparation in the same way that he did in his cases. I employ the ordinary solution of adrenalin chloride in the strength of 1 part in 1,000, applied on a piece of ordinary lint folded double and of sufficient size to cover the front of the neck from the hyoid bone above to the top of the manubrium sterni below and extending laterally to a line drawn vertically downwards from the ear on each side. Just enough of the solution is used to moisten the lint without making it drip; there is probably no reason why more of it should not be employed at a time if it were not for its expense; the cost, indeed, is the chief objection to the treatment. There seems, again, to be no reason why the lint thus steeped in adrenalin chloride solution should not be renewed twice or three times in the twenty-four hours and applied continuously, but as patients who are up and about do not as a rule like applications to their throats during the daytime, one's ordinary habit is to prescribe the application at night only. The lint is covered with gutta-percha tissue and the latter kept on with a suitable neck-band or bandage; it is generally advisable to pin the latter to the neck of the nightgown, so as to prevent the whole application from twisting round the neck and becoming altogether displaced from the thyroid gland region during the night. As a rule, one also prescribes extract of malt and iron in two-drachm doses three times a day; the type of malt and iron that I personally prefer is that which is made up by dissolving two parts of pyrophosphate of iron in three parts of water and then mixing this with 95 parts of thick, dark extract of malt.

It is impossible to give statistical proof of the value of this treatment; one is obliged to be guided

by personal opinion, and I quite agree that this is unsatisfactory, because one cannot help being biased. Nevertheless, from experience, both in the out-patient department of the hospital, and amongst others who are better-to-do, one can assert with certainty that no ill effects accrue from it and that, so far, one is strongly of opinion that the patients tend to increase in weight, diminish in nervousness and to improve in general health under this treatment, even when other measures have been tried and have failed; and amongst out-patients this applies even to patients who, on account of the need to continue earning a wage, have been unable to rest up in bed even for a time, but have had to continue working at occupations which have been either physically or mentally laborious—typewriting, for instance, or clerking, or as a factory hand, and so forth. One does not claim that it is more than a palliative remedy, but it is certainly one that may be worth while knowing of and trying in some, if not all, cases of Graves's disease.

The next point that I should like to remind you of is

THE VALUE OF VERY SIMPLE CO-ORDINATING EXERCISES IN THE TREATMENT OF ATAXIA,

especially that variety which occurs in *tabes dorsalis*. Many a patient suffering from this disease becomes bedridden, or, at any rate, confined to a chair or couch long before he need have been had been taught to practise simple co-ordination, especially with his legs, in the earlier stages of the malady. This point was first proved by German physicians; it is beginning to be known in England, but knowledge of it is not nearly so widespread as it might well be. A Bristol publishing firm have issued at the price of half-a-guinea a sort of draught-board with circular and diagonal lines and a booklet of directions by means of which the patient can be taught to practise co-ordinating movements with his feet; but there is no need whatever for any complicated diagrams or apparatus. If the underlying principle of the treatment is understood each of us can devise simple exercises which may be varied week by week or month by month, the patient's interest in them being thereby maintained, though care should be taken to keep them simple, and not make them either long or complex. It is important to bear in mind always that the exercises are not required for the purpose of increasing the strength of the individual muscles, for this is already good as a rule, except in quite a late stage of *tabes*; the purpose of the exercises should be to call for as little fatiguing effort as possible, but a maximum of precision necessitating the co-ordinated use of opposing groups of muscles. It is easier to demonstrate two or three simple movements than it is to describe them. One of the simplest is to have four or five pennies or small pieces of paper and to throw them upon the floor at hazard in front of the patient's feet within easy reach, but not too close together. If his ataxy is considerable he may be seated in a chair; if he can manage the movements standing up, so much the better, and if need be he can use a stick or the back of a chair as a support; or he may practise the movements first sitting, then standing. In order to touch each coin in succession accurately with the point of his shoe, or with his big toe, if his foot is bare, he will bring into play most of the muscles of his thigh, leg and foot; and if the movement is continued accurately a marked degree of co-ordination is required. When the patient is already ataxic he will touch each coin clumsily, or may put his toe down not on the coin at all, but somewhere on the floor near it; by practice, however, he will re-co-ordinate the movements of the leg and foot

muscles until presently his coin-touching efforts will be much more precise and accurate than they were to start with. By varying the position of the coins, or by varying the order in which they are touched, sometimes numbering them from left to right, sometimes from right to left, sometimes touching them not in the order 1, 2, 3, 4, but in the order 1, 3, 2, 4, or 1, 4, 3, 2, and so forth, it is possible by means of this simple device and without any costly apparatus to do a great deal towards staving off the time when the patient will no longer be able to walk. It has been estimated that as much as ten years can be added to some of these patients' lives in this way. It should always be insisted upon that the patient must not go on with the movements at any one time so long as to make his limb fatigued. Their purpose is not to cultivate physical strength, but to teach the muscles once more how to act together to the best advantage; it is a great deal better to practise the co-ordinating movements for two or three minutes at a time half-a-dozen times a day than it is to have a longer and more fatiguing *séance* all at one time.

Another very simple exercise which these patients may undertake is for them to stand with their feet sufficiently far apart to prevent their tumbling over, and then to practise rising, not suddenly or quickly, but slowly and steadily from the level foot on to the tips of the toes, and then, not to drop suddenly down on the heel again, but to go down slowly, and with precision, from the tip-toe position until the heel once more touches the floor. At first some of the patients will find this a very difficult movement, and it may be necessary for them to hold on to a chair-back or something of that kind to prevent their falling over in their efforts to rise slowly on to tip-toe, but later the power of co-ordinating the different muscles concerned in the act very often becomes wonderfully restored even when the first attempts seemed absolutely hopeless.

A third kind of co-ordinating exercise which interests these patients is for them to stand—at first holding on to a chair-back or other support, but later with no support at all—and to raise one foot off the floor and place it with as much precision as possible on a marked spot on the seat of a chair; and then, after a pause, to raise it from the seat of the chair and to replace it, not with a sudden drop, but with a steady downward movement on to the floor. Each such exercise may be repeated with each foot in turn, and there is a certain amount of co-ordinating effort demanded of the passive leg and foot each time, as well as of the one that is being raised on to the chair. If the patient is already so ataxic that he cannot raise the foot so high as on to an ordinary chair-seat, something less high may be used instead—a footstool or a box, for example.

It is clearly easy to devise a great variety of other different movements of a similar kind, all having the same purpose, namely, the re-education of the power of co-ordination in the legs; and the trouble taken in this direction in cases of *tabes dorsalis*, disseminated sclerosis, ataxic paraplegia and other affections associated with ataxy is well worth while and well repaid by the improvement in the patient's power of standing and of walking in many cases.

The next therapeutic point that I should like to refer to is a very simple one indeed, but again and again it has proved extremely useful. It may be labelled

THE OPEN-EYE TREATMENT OF SIMPLE INSOMNIA.

I have no idea to whom we owe the first insistence upon this point, but I have found that patients are very seldom told about it, so that one cannot but think that its importance is realised too little.

When, without obvious external cause, such as too close a room, too many bed-clothes, or too few, a visceral pain, or some other cause of that kind, a person cannot get to sleep at night on account of what is generally called "simple insomnia," in the great majority of instances he lies in bed with his eyes tightly closed, restlessly rolling from side to side with all kinds of thoughts streaming through his mind and keeping him awake. It has always been an impossibility to me personally to count imaginary sheep passing through a gap in the hedge or to make any of the similar concentrated mental efforts that are so often prescribed; but I have always found it very easy, to begin with at any rate, to lie with my eyes wide open and, if possible, fixed upon some definite part of the ceiling or window, or other point that may be just visible. In a very short time an increasing difficulty in keeping the eyelids up develops; the lids become heavy, but if one still persists in opening them to look again at the chosen spot as often as they tend to shut, it is surprising how soon oblivion supervenes; there are few things so soporific as a fixed intention to keep awake when one is in the dark, especially if the effort in that direction is accompanied by insistence upon keeping the eyelids open. Most patients are surprised at being advised to do what seems to them in the first instance the very opposite of what would appear the best course to follow, but when they try the effect they are generally delighted with it.

One other great point about simple insomnia is that it is seldom the insomnia itself which does so much harm as does the worrying at the fact of not being asleep. The individual lies in bed making a forced effort to sleep, and saying to himself how annoying it is his not sleeping like this; he has come to bed with the special object of getting a good night's rest, because he knows he has a heavy day's work to-morrow; and now he cannot sleep. In a few minutes this worry grows upon him so much that he rolls from his right side over on to his left, and tries again in this new position. Before this has been given a proper trial he has decided that he will roll right over. And so he goes on; his restlessness increases, and by simply worrying at not sleeping he may successfully keep himself awake for two or three hours or longer. Many such patients have derived immense benefit from being told that the tired feeling next day is due to the worry at not sleeping more than to the not sleeping itself. It is possible to cultivate a sense of calm which assists the cure of insomnia without the use of any drugs. A man may lie awake all night and it will do him no particular harm if he does not worry at it. If he persuades himself fully of this point and prepares to lie awake placidly all night he will often fall asleep in quite a short time, and much to his own surprise, especially if he adopts the "open-eye" remedy soon after he finds that he is not falling asleep in the ordinary way.

The next therapeutic point which I should like to draw your attention to is

THE VALUE OF THE SKIPPING ROPE IN THE TREATMENT OF CHRONIC CONSTIPATION.

A very great deal of what may be called "chronic simple constipation" is actually the product of treatment by medical men; it is so easy to prescribe a laxative, or, worse still, a purge, for a patient who complains that he is liverish and that his bowels do not act as well as he would like them to. The prescription is apt to be repeated. The patient may even be given a supply of pills to keep by him, one or two to be taken when he feels he needs them. The habit of taking them grows. Patients themselves often take purges in the form

of proprietary pills without advice, and get into the way of depending upon them. Some parents prescribe purges for their children with too little thought. I do not wish to go into this point in all the detail that I should like, but I feel very strongly upon the subject of the abuse of purgatives, and the tremendous amount of constipation and worse results that develop from it. I am accustomed to say that many persons who begin with cascara sagrada or Epsom salts at fifteen years of age have to take to calomel or podophyllum or something stronger at twenty-five or thirty, and have to increase the dose and the strength of what they need to move the bowels year by year until, figuratively speaking, in many instances at forty or forty-five gunpowder will hardly do it. This, of course, overstates the case, except in the rarer instances, but there can be no doubt that a very great deal of chronic constipation, intestinal toxæmia and the protean results of this can be directly traced to the treatment of simple constipation by purgatives without first trying non-medical means. The first and most important of the latter is what may be called for short the cultivation of the regular habit, the patient trying to have his bowels moved each day immediately after breakfast, or at some other time if more convenient, but, as far as possible, at the same time each day, until the bowels begin to get into the habit of wanting to be moved at this time rather than at any other. There are various ways of assisting the re-development of the diurnal habit of the colon; these have been already discussed by Sir James Sawyer, M.D., F.R.C.P., F.R.S.Ed., in his work entitled "Practical Medicine." I wish, however, to lay particular stress upon one very simple accessory means of relieving chronic constipation, and that is the use of the skipping rope for sixty seconds after the bath in the morning, and, if need be, for another sixty seconds at some other period of the day. The vigorous jolting movements given to the whole body, the increased respiratory movements, the increased action of the heart and the exercise given to the vaso-motor system in controlling the alterations in the blood supply produced by the exercise are all beneficial, except under exceptional circumstances, such as definite heart disease and the like, but over and above this it seems probable that every time the patient skips over the rope, thus raising his legs off the floor, the sudden sharp contractions of the psoas and iliacus muscles directly influence the colon in front of them and thus assist the activity of the latter, possibly increasing peristalsis, especially in the cæcum and in the sigmoid colon. Very frequently the effort of skipping even for so short a time as sixty seconds causes flatus to be passed, showing that the movements have an immediate effect upon the bowel contents. The exercise occupies so short a time that it can be continued daily without any particular inconvenience or without its being omitted on account of its complexity or duration. Many individuals who have been sufferers from chronic constipation have found that the use of the skipping rope in this way in addition to the cultivation of the regular diurnal habit cures habitual constipation without the need for resorting to purgatives at all.

(To be concluded in our next.)

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Herbert French, M.A., M.D. Oxon., F.R.C.P.Lond., Assistant Physician, Pathologist and Lecturer to Guy's Hospital. Subject: "Some Therapeutic Points."—conclusion.

ORIGINAL PAPERS.

THE NEUROLOGY OF THE VISUAL SYSTEM.

A Short Series of Original Papers.

By HARRY CAMPBELL, M.D., F.R.C.P.,

Physician to the West End Hospital for Diseases of the Nervous System.

PAPER III.

B.—LESION CAUSING HEMIOPIC EFFECTS.

We have next to consider the lesions which cause hemiopic effects, paralytic (hemianopia) and irritative (hemiopic visual sensations and hallucinations). The latter only occur when the lesion is in or near the cortex. When the lesion involves the chiasma, the blindness may affect both temporal or both nasal halves of the retina, or one temporal or one nasal half. When, however, a destructive lesion involves the hemiopic tract behind the chiasma, it always causes blindness in the corresponding half of each retina (homolateral hemianopia). When, *e.g.*, any part of the right hemiopic tract is destroyed, blindness of the right half of each retina occurs. Inasmuch as this causes blindness in the left half of the visual field, it is spoken of as "left hemianopia." Similarly, blindness of the nasal half of each retina is known as "temporal hemianopia"; and blindness of the temporal half of each retina as "nasal hemianopia." [These two forms are sometimes termed heterolateral hemianopia.]

The hemianopic patient may be unconscious of his defect. When conscious of it, he often thinks he is blind in one eye—the eye, *i.e.*, on the side of the blind half of the visual field. In right-sided hemianopia reading is difficult: the patient can see the word he fixes, but not the following one. In left-sided hemianopia, the reading of a single line is easy, but it is difficult to pass from one line to the next. In hemianopia, no reflex blinking occurs on suddenly introducing an object, say, the point of a finger, into the blind portion of the field. A patient with homolateral hemianopia asked to bisect a straight line drawn on a piece of paper, makes the portion corresponding to the blind side the larger.

Lesions of the chiasma.—In these lesions there is often evidence of optic atrophy. Destructive lesions give rise to heterolateral hemianopias, as indicated by Fig. 11. A lesion at *a* causes unilateral

FIG. 11.—Lesions in optic commissure.

nasal hemianopia. A lesion involving *a* and *a'* causes bilateral nasal hemianopia (Fig. 12). A lesion at *b* causes bi-temporal hemianopia.

A lesion involving *a* (or *a'*) and *b* causes blindness of one eye and temporal hemianopia of the other. Of these, the last two are the most common. In bi-temporal hemianopia

the visual difficulty is greater than in the bi-nasal variety, inasmuch as the temporal visual fields are more extensive than the nasal.

The chiasma may be damaged from lesion of the pituitary body (as in acromegaly), the sella turcica, the base of the brain, or of the chiasma

FIG. 12.—Bilateral nasal hemianopia. Observe that the blindness does not extend up to the middle line.

itself, or from fracture of the base of the skull. The pial investment of the chiasma is apt to be involved in tubercle, gumma, gummatous meningitis, and epidemic cerebro-spinal meningitis. Since the recesses of the third ventricle overlie the chiasma, any increase of fluid pressure within this chamber may press upon the chiasma. The increased intra-ventricular pressure which may result from cerebral tumour is a frequent cause of visual defect in this disease.

Destructive lesions of any part of one hemiopic tract (See Fig. 10) behind the chiasma (*i.e.*, the optic tract, the external corpus geniculatum, pulvinar, the retro-lenticular portion of the internal capsule, the optic radiations, and the hemiopic cortex) cause homolateral hemianopia: there is blindness in the corresponding half of each retina, so that the patient is blind as regards the opposite half of the visual field. Lesions of the pulvinar are said to cause hemianopia.

Lesions of the optic tract.—Lesions of the optic tract, like those of the chiasma and optic nerves, may give rise to optic atrophy. It is rare to find isolated lesions of the tract, which is more likely to be affected in conjunction with the chiasma, the corpora geniculata, the corpora quadrigemina, and the thalamus. It is supplied by small end-arteries, and blockage of them may cause hemianopia. The central end is relatively often involved in softening, together with the corpora quadrigemina and the geniculate bodies. The tract may be pressed upon by tumours, especially those involving the temporal lobe; or tumours may grow from the tract itself.

Besides causing hemianopia, lesions of the optic tract give rise to hemiopic loss of light reflex (Wernicke's sign). These lesions often involve the ocular nerves, sometimes even the fifth and the seventh, the resulting paralysis or anaesthesia being on the side opposite to the hemianopia. Hemiplegia and hemianæsthesia are rare.

Lesions of the external geniculate body.—Hemianopia has been known to result from disease of this structure. Some observers contend that the retinal fibres preserve their relative position as far as the external geniculate bodies, but no further. According to Henchen, a lesion in the superior parts of one corpus genic. ext. gives rise to a scotoma in the lower part of the visual field, and a lesion in its inferior part to a scotoma in the upper part of the field.

Lesions of the retro-lenticular portion of the internal capsule.—The hemianopia resulting from lesions here is often accompanied by hemiplegia

with hemianæsthesia. The hemianopia may be permanent, but transient hemianopia is not infrequent after a stroke. In the hemianopia accompanying hemiplegia the patient cannot see on the paralysed side. If the lesion is on the left side there may likewise be word-blindness (from involvement of the angular gyrus). All varieties of aphasia may, however, accompany hemianopia. The most frequent lesions in this region, as well as in the optic radiations and the hemiopic cortex are: hæmorrhage, softening, and tumours.

Lesions of the optic radiations and the hemiopic cortex.—These constitute the commonest causes of hemianopia. This results most frequently from lesions in the cortex, and next in frequency as a cause come lesions in the optic radiations. In either case the usual lesion is softening (*e.g.*, from endarteritis). The hemiopic cortex is supplied by the occipital artery, more especially by its third branch. Transient hemianopia may result from lesions in the neighbourhood of these parts.

Sudden cortical hemianopia is not rare in connection with vascular lesions. The occurrence of bilateral cortical hemianopia is facilitated by the juxtaposition of the two hemiopic areas which face one another. This renders the two liable to be involved in a single lesion. They may also be affected by consecutive lesions.

Quadrantic hemianopia (*i.e.*, blindness in symmetrical quadrants, or even sextants, in the corresponding half of each retina) may result from a lesion in the hemiopic cortex or subjacent radiations suggesting that the visual fibres maintain a definite relation to one another in the radiations and the cortex, the retina being as it were projected on to the cortex. Thus a lesion in the upper lip of the calcarine fissure (*i.e.*, in the cuneus) is said to cause upper quadrant blindness of the retina (lower segment of the visual field); one in the lower lip, lower quadrant blindness of the retina (upper segment of the visual field). A double quadrant blindness from bilateral cortical lesion would cause a horizontal hemianopia. No such case has been verified *post mortem*. This rare form of hemianopia has also been attributed to a symmetrical lesion of the optic nerve fibres.

Cases of hemi-achromatopsia and hemidyschromatopsia have been described in connection with cortical lesions, and Ethridge Green has postulated two distinct centres in the occipital lobes—one for colour and the other for simple luminosity. There may be either a weakening of colour vision generally, or blindness as regards special colours, *e.g.*, red and green, and less frequently, yellow and blue. Some doubt the existence of genuine hemi-achromatopsia, attributing the reputed cases to incomplete hemianopia.

With hemianopia (especially when right-sided) there may be dyschromatopsia in the retained halves of the visual field.

An irritative lesion in the hemiopic cortex may give rise to hemiopic sensations and hallucinations, which are referred to the blind side of the visual field.

The visual field in homolateral hemianopia.—Macular vision is practically always retained. When the lesion involves the optic tract it may happen (very rarely) that the mesial margin of the blind area passes through the macula. Generally, however, it falls short of this.

The retention of vision in the central part of the field in homolateral hemianopia is explicable

on the assumption that the macular region of each eye is widely represented in the visual cortex of both hemispheres. That the cortical centres for macular vision are distinct from the hemiopic is shown by the fact that macular vision is retained when both hemiopic centres are destroyed. In this case double homolateral hemianopia is produced, leaving limited central vision, which, unless especially tested for, may escape both patient and physician. The term "cortical blindness" has been incorrectly applied to this condition. In hemianopia there may be considerable concentric narrowing of the retained visual fields, especially on the side opposite the lesion.

Functional hemianopsia.—This may occur in megrim, as part of the epileptic aura, and in connection with the epileptiform attacks of general paralysis of the insane. In megrim the hemianopia, like the other visual phenomena (*teichopsiæ*), ushers in the attack. It is due to a symmetrical patchy blindness: the sufferer, *e.g.*, may be able to see the whole of a person's body save only the head; or perhaps only one half of the head may be visible. The blindness in this case appears to be due to a contraction of retinal arteries, a phenomenon which has been actually observed during an initial phase of the attack.

Hysterical hemianopia has been described; the existence of such a form is doubtful. Hemianopia is said to occur occasionally in uræmia.

C. LESIONS OF THE ANGULAR GYRUS.

This gyrus is closely associated with vision. The macular region in both retinae is said to be represented in each angular gyrus. Bilateral destruction of it causes total blindness. Unilateral destruction leaves vision intact. (Sharkey has, however, recorded a case of crossed amblyopia from lesion of one angular gyrus.) Lesion of the left angular gyrus causes word-blindness (inability to recognise written or printed words although they are seen), and occasionally psychic blindness (inability to recognise objects of any kind, although the patient sees them); or, again, there may be loss of the sense of orientation—the loss of visual memory, *e.g.*, may prevent the patient from recognising a familiar locality. [According to Marie pure word-blindness only occurs in sub-cortical lesions. Word-blindness is not, he contends, due to involvement of the angular gyrus (supplied by the middle cerebral), but to a lesion situated in the territory of the posterior cerebral.] Lesions of the right gyrus cannot be diagnosed.

Irritative lesions of the angular gyrus may excite a visual aura, consisting either of crude visual sensations, such as sparks, or visual images (hallucinations). A visual aura may occur both in idiopathic epilepsy and in Jacksonian epilepsy. Visual hallucinations may occur in insanity and delirium, such as that produced by fever or drugs (*e.g.*, *cannabis indica*, alcohol).

The motor effects produced by irritation of the angular gyrus are considered later.

(To be Continued.)

In opening the new sewage works the other day, built by the Brentwood and Billericay joint authorities at a cost of £20,000, Dr. Thresh, Medical Officer of Essex, said that they were unlikely to be superseded for many generations, as the bacteriological process had been so improved that in these, the most modern works in the kingdom, the sewage effluent could be made pure enough to use over again as drinking water.

"VITALISM" IN THE PRACTICE OF MEDICINE (a)

By JOSEPH O'CARROLL, M.D., F.R.C.P.I.,

Physician to the House of Industry Hospitals, Dublin; President of the Section of Medicine in the Royal Academy of Medicine in Ireland.

HAVING briefly sketched the work of the Section during its thirty years of life, Dr. O'Carroll proceeded:—All of us physicians may be said to undergo an evolution in three stages. At first we look at Nature—morbid Nature as it seems to us—with wonder, tempered with curiosity; then with easy confidence we set ourselves to combat the morbid impulses of Nature, with what poor success in any one generation we know too well; and finally we learn that the supposed morbidities of Nature are either the necessary wearing out of a finite machine or the result of the inter-action of forces, often vital ones, in which the human organism for a time or for good gets the worst of it.

Professor Schäfer, in his recent address to the British Association for the Advancement of Science, seemed to take the view that the phenomena of life may ultimately be capable of being stated in a series of chemical equations; in other words, that the activities of the simple cell, and, therefore, of the most compound organism, are an expression of the reaction of its chemical constituents to those of the medium in which it lives, or of the antagonist with which it strives for life. "We may fairly conclude," he says, "that all changes in living substance are brought about by ordinary chemical and physical forces. . . . At the best, 'vitalism' explains nothing, and the term 'vital force' is an expression of ignorance which can bring us no further along the path of 'knowledge.'"

He supposes a gradual transition "from material which was lifeless, through material on the borderland between inanimate and animate, to material which has all the characteristics to which we attach the term 'life.'"

Now, I do not think that this wholly mechanical view of life will commend itself to the student of internal medicine. Every man must work on some hypothesis or other, and this purely mechanical explanation of life is, it seems to me, entirely unhelpful to the physician. Far be it from me to say that the chemico-mechanical view is utterly wrong. I recognise that it goes a very long way in explaining most of the processes which we are accustomed to call vital. The law of gravity is as compulsory in a living man as in a corpse; filtration, osmosis, liquid tensions, all obey their several laws in the living body as in the laboratory; and chemical reactions, no doubt, are equally obligatory. But the living body, I believe, possesses a power outside of all these physical forces—namely, the function of resistance, adaptation, or accommodation; that function of life is the very corner stone of evolution, and is a new force outside and beyond those which enter into physico-chemical reactions.

The detritus of some Alpine height will as certainly as possible pursue a continuous descent towards the sea, and no fragment of it will ever have the power to lift itself backwards by the millionth part of an inch towards the boulder from which it originally broke away. Its destiny is simple and immutable unless in so far as some living thing may modify it.

But look at the world of life on the other hand. Roughly speaking, one may say that survival depends upon resistance to gravity, resistance to friction, resistance to heat and cold, and to a thousand other destructive forces. Resistance is the mark of life; partial resistance, coupled with partial acquiescence, in biology as in politics, may be termed accommodation, and to this power of accommodation or compromise is largely due the survival of many forms of life.

Man has learned to accommodate himself to physical surroundings and to biological infections which in earlier ages were much more fatal than they

are now. The stress of modern life would have been intolerable—physically intolerable—in the ages in which a man had done a good day's work when he had killed enough game for two or three days' food, and had gorged himself into a condition of somnolent repletion. Under the press of competition he has learned to eat more temperately and to work harder. Yet now and again an individual here and there breaks down under the strain; his power of accommodation gives way, and he is said to become neurasthenic. He becomes intolerant of the noise, the bustle, the anxieties, the ambitions of civilisation; and then we put him to bed, we give him plenty of food, and as far as possible we shut him off from contact with the outside world. We try to reproduce the condition of the over-fed savage in his rock-cave, in the hope that after a time he will come forth fit to hunt with his fellow-man again. The breakdown of the neurasthenic only accentuates the accommodation of the majority of men to more strenuous conditions.

Man has always had to fight for existence with other forms of life. The microbic organisms have at all times been his deadliest enemies. Yet we have abundant evidence that now he makes a much better fight than in former ages. The infective fevers are less deadly in a community in which they are endemic than in one to which they are freshly introduced. In the one case the continuous entity Man—what I may term the brotoplast—has accommodated itself to the microbic enemy, and in large measure survives; in the other case it has not yet acquired the faculty of accommodation, and for a time it largely succumbs. Tuberculosis has become less deadly, syphilis has become attenuated in virulence, leprosy tends gradually to become more and more limited in its distribution. If this increased resistance depends, as no doubt it does, on chemical changes in our constitution, it is no less true that only in a living organism could such change have come about.

Yet it would be a fatal confidence to ignore the fact that if man has the power of resistance and accommodation, the microbic organisms have similar powers. Little as we know about them, this at least is certain, that though the human body may be able completely to antagonise some of them, as witness the finite fevers, such as measles and smallpox, yet there are others which it can often only keep in check without absolutely killing or eliminating them. The persistence of the bacillus in the typhoid-carrier, the recrudescence in apparently cured tuberculosis, the cropping up of syphilitic manifestations when cure had long seemed complete, are suggestive of the view that the microbe-race fights for survival with a tenacity and a success which are utterly inexplicable as due to mere chemical force as we understand the term. That micro-organisms can acquire immunity to the human anti-bodies is common knowledge. Experience of the salvarsan treatment appears to show that the *spirochæta pallida* may acquire a certain power of resistance to arsenic. A succession of small doses resting unsuccessful, a full dose may fail equally; probably because the organism has become habituated to the poison, as if it were one of the arsenic eaters of Styria. This may be the reason why in pernicious anæmia arsenic administered by the mouth may have a temporary success while it ultimately fails. I am myself disposed when I next meet a case of that disease which has not been treated by arsenic, to try an injection of salvarsan in the hope that the causative agent may be annihilated by a dose which will not be intolerable for the host.

The accommodative process is active not merely between organism and organism, but within the individual living thing is visible in direct proportion to the complexity of its organisation. The form, structure, and function of the various parts of a compound organism, each dependent for safety not merely on its own activities but on those of other parts, are an expression of that accommodative process which I take to be such an essential mark of life. The original cells of the fertilised ovum have surrendered their individual liberty and made an accommodation or pact by which division of labour and differentiation of form

(a) A Presidential Address to the Section of Medicine in the Royal Academy of Medicine in Ireland, at the Inaugural Meeting of the Session of 1912-1913.

secure the healthy development of the whole community into what we call an individual. Those which are marked off to be nerve cells—comparatively few—are the life-peers of the human organism. Their dignity and function are coterminous with their life; but they have no heirs. On the other hand, the lower class cells—that is, the least differentiated—breed freely, have a continuous succession, and may from time to time leap the barriers of form and function allotted to them, forming reparative structures such as a scar, or definite new growths such as cancer. Even in this last eventuality the more orderly cells can be seen to constitute themselves into an army of resistance, which makes a continuous but perpetually losing fight against the rebel cells constituting the new growth.

In the progress of common diseases this vital accommodation is marked; and I venture to assert that no one can form a true estimate of disease who does not at least try to separate the processes which are truly morbid from those which are resistive, conservative, and accommodative. Take, for instance, the common arterio-sclerotic syndrome. A heightened blood-pressure and perhaps an unduly perceptible artery-wall hint at the establishment of the disease, whatever its cause. Then a heart-beat more forcible than normal, and perhaps increase in the daily quantity of urine, and the presence in it of a trace of albumin, complete the clinical picture. I hold that he who would understand and treat the disease—if, indeed, we are ever likely to understand it fully—must recognise that for a time at least the events in it are protective for the general organism, and that the end approaches in proportion as each protective process breaks down. Thus in this syndrome the cardiac hypertrophy and the polyuria are probably protective. The tumult of the heart and the albumin incontinence of the kidney probably indicate the failure of these two lines of defence. No doubt the arterial change which first attracts attention is itself also protective, and by no means morbid. At least we may say that the arterial pressure commonly falls away towards the end, accompanied by a corresponding deterioration in the condition of the patient. The *materies morbi* is evidently behind all these symptoms.

This view of disease might seem to deprecate all treatment. By no means. It suggests only that we should try to set symptoms in their professional order; that we should aim at discovering and treating the primary cause if possible; and that we should congratulate ourselves on the diminution or disappearance of the secondary symptoms only if the general condition of the body as a whole is therewith manifestly improved. In other words, I wish to inculcate the greatest respect for symptoms which in their early stages I believe to be defensive, and which, as they represent the effort of this or that tissue or organ to defend the whole organism even at the cost of ultimate damage to themselves, I conceive to be essentially vital and not chemico-physical phenomena. Taking this very case of arterio-sclerosis, let me suggest by way of illustration what I take to be an error in treatment. A person showing this condition develops after some time a little puffiness about the ankles. My reading of the cause of this is that probably the kidneys are becoming a little unfit to maintain their line of defence; but the patient thinks he has dropsy, and claims instant removal of a condition which he takes to be a sure forerunner and cause of death. We yield to his prayer, and administer a brisk diuretic. The œdema disappears like magic, and for a few days we enjoy the credit of having performed a miracle. But a swift retribution follows in the shape of more dropsy, less urine, and the more or less rapid super-vention of uræmia. Respect for the vital and accommodative resistance of the human body should have taught us to hesitate before interfering with a little harmless œdema by direct stimulation of the organ of whose fatigue or failure it was the sign.

This is not to say that in any given case we are to stand by admiring the process of nature and doing nothing. This matter of œdema and dropsy will serve to exemplify my position. We may take it for granted

that there is a continual circulation of the fluids of the body from the heart to the tissues (including those of the heart itself) and from the tissues back to the heart. The loss of fluid from the skin and the lungs will normally be balanced by the intake from the alimentary tract, and may, for the purpose of my argument, be ignored. When the circulatory mechanism for any reason fails, there must be a tendency to stasis in the circuit, and stasis would mean death to the organism. Stasis is put off by the occurrence of dropsy. Where does it first show itself? In the fine lymphatic passages surrounding the ultimate and least differentiated tissue cells and in the larger lymphatic cavities. We have latterly thrown over the old mechanical view of dropsy; thanks largely to the labours of the French school, we now incline to the chemical explanation; but I venture to assert that while both mechanical and chemical explanations are still necessary, they are insufficient to account for the special localisation of dropsical fluids. That localisation is dependent upon a vital selection by which it is placed where it can do least harm; and I may add that it always, or nearly always, occurs when the kidneys have already done their best to relieve the relative plethora of the circulation, and have begun to fail. Dropsy so localised is for a time harmless. Any attempt to remove it by stimulating the kidneys to further effort is sure to fail; when it becomes obnoxious by its bulk it is best removed by paracentesis. This view gives to dropsy an essential value as a vital effort on the part of the organism to relieve the main circulating system; the blood is permitted to unload the least essential of its elements in the interstices of the least essential tissues, which in their turn live much longer than if they resisted such a burden. This is no fanciful view. Over and over again in hospital we have seen dropsical patients kept alive for terms which seemed impossible at their admission, by leaving their dropsy untreated till it reached a pressure which just incommoded the circulation or the breathing, and then removing it by tapping. More than five years ago a woman was admitted into hospital under my care, apparently dying with mitral incompetence, dropsy, and albumin in the urine. She died only a month ago, having had abdominal paracentesis performed more than a hundred times. During four years she had been able to go home for a few days between each tapping, when the weather was fine, while she stayed with us entirely during each winter.

I contend, then, that while the living organism is subject to all physical forces, it has a force of its own—a vital force which determines it to preserve its own individuality. That force, present in all its several structures, determines each to preserve its own existence, while at the same time it is dependent for perfect function upon the health of the other structures which go to make up the organism. In health the distribution of function is so equilibrated that we can recognise no part as being more perfect or less perfect than another. In that falling away from health which we call "disease" it commonly happens that structures and tissues fail in proportion as they are more highly specialised or have been later in development. But at each stage of degradation defensive works are set up by tissues lower or simpler in structure and of older birth, so that the most ancient of our tissues are the last to die. A good deal of the essence of a scientific treatment of disease consists in the full use of these lower defences before we attempt to recapture and rehabilitate the higher positions which have been lost or put out of action.

All this implies something akin to intelligence or purpose in the living cell or in the community of cells which constitute the individual, by which it aims perpetually at not ceasing to be, and by resistance and compromise adapts itself to forces from within or from without which tend to its destruction. And as the various groups of cells of different function which constitute a higher organism live a social life, in which each is dependent upon and acts in defence of the others, I recognise herein the very beginning of a social morality. That morality is based upon mutual interest and the common good. When organisms of

similar kind multiply they retain as individuals, and as a community commonly develop on a higher level this social morality. In the case of lower organisms than ourselves we usually call the various manifestations of this social morality by the name of instincts—a name which explains neither their origin nor their purpose. If we recognise the defensive and accommodative purpose of these instincts we give them a moral sanction, and we accept morality as one of the functions of life. Thus the vital force which, in my conception, with all the various so-called physical forces, conditions the existence of a living organism or community brings to such organism or community a power of resisting dissolution by mere physical forces; and in higher organisations this resistance is made efficient by a sub-division of function and a mutual interaction of parts which, in a human community, would be said to be the result of a natural morality. I see no reason for denying to simpler organisations a simpler and more embryonic, though none the less real and beneficial, morality.

But I do not think that anyone can imagine a moral sense, no matter how rudimentary, being instilled into a mass of "colloidal slime" by any grouping of chemical and other physical forces. If this is unthinkable, then Professor Schäfer's vision of life being some day produced anew by the chemist from inorganic matter must remain a dream of the impossible.

This very crude intrusion of mine into a more or less abstract domain will, I hope, be acceptable to you for the sake of its lesson. That lesson is that we should, in our dealings with sick humanity, try to discriminate between those symptoms and conditions which are harmful to life and those which are defensive of it; that we should approach Nature as we see her, with respectful timidity, not with boorish temerity; and that we should think of ourselves as servants in the court of a great and wise and beneficent, but unfortunately dumb, queen whose will has to be read by signs, according to our individual ability.

To accept the chemico-physical theory as the full explanation of life would be to hand ourselves over to a perfectly hopeless determinism. While it may possibly be true that Professor Schäfer's "colloidal slime" may from time to time take on the form and functions of life—in other words, that the production of life is continuous—such a jump into life must mean the taking on of qualities which were in no degree inherent in the original material. To say that such qualities—defensive, social, and moral—are explicable on chemical grounds accounts for such change no more than "vitalism" does, and it leaves us with the uncomfortable feeling that while it deprives the term "chemical" of all definite value, it robs our conception of life of all that it connotes in the long story which begins at or before the amœba and ends with human civilisation.

A PATHOLOGICAL DIGEST (a)

By H. MACNAUGHTON-JONES, M.D., M.A.O.,
M.Ch., F.R.C.S.I., F.R.C.S.E.

MR. PRESIDENT AND FELLOWS:—I cannot express in words my appreciation of the unexpected and exceptional honour that the College of Surgeons conferred on me when the President and Council invited me to address its Fellows. That appreciation was naturally accompanied by a sense of my inadequateness, but acquiescence was to an extent justified by the subject matter of the theme on which the Council proposed that I should speak.

This was to give a brief description of some of the most interesting and important pathological specimens which the Council honoured me by accepting, and still further by placing in a separate collection in its historic Museum. That collection is not altogether gynaecological, and in the large album that accompanies it there are several miscellaneous original drawings representing matters more especially of ophthalmological and otological, as well as a few of general surgical interest. Of a large number of the specimens

there are microscopical sections, showing their histological features. These I shall add to the collection after classification and arrangement according to their bearing on the macroscopical characters of the morbid growths or pathological changes. Clinical histories will accompany the great majority of the specimens. This I regard as most essential for teaching ends. It must be remembered that the gynaecological specimens which from time to time I considered worth preserving were entirely obtained from private operative work.

I propose to ask your attention to some examples of morbid conditions illustrated by these specimens, though I can only select a very limited number of each. I shall consider them under the heads of uterine, ovarian, tubal, and vaginal. I shall then demonstrate some of the more interesting microscopical sections which are included in the collection.

Necessarily, several have already been referred to in medical literature.

Uterine Myomata—Degenerations.—My largest solid myoma is represented in the album, as it really was too large to preserve. The photograph shows its actual size. It weighed twenty-eight and a-half pounds, and measured fourteen inches in length by thirteen and three-quarters at its widest part. It was covered by a dense capsule. The patient was a multipara, æt. fifty. Its origin was peculiar, growing mainly from the left broad ligament; but it had also a root in the adjacent cornu of the uterus. In its removal the bladder, which was adherent to the tumour, was opened. The wound in it was closed, and the patient made an excellent and permanent recovery.

This myoma which I show you was my next largest, as you will readily understand from its length. It reached from the pelvic floor to the diaphragm, and by pressure on the heart and lungs, caused dyspnoea and tachycardia. It had somewhat of an hour-glass shape. There were some pelvic and bowel adhesions. The patient never rallied from the operation, and appeared to die simply of shock on the third day. On careful examination of the tumour, a portion of a divided ureter was found attached to it. There were no urinary symptoms, and she secreted urine in fair quantity. This has been my only case of injury to the ureter. Probably I was not as careful as I should have been in its isolation.

This tumour is a good example of mucoid and *calcareous degeneration* with necrobiosis in a myoma. The patient was æt. 48. The tumour was increasing rapidly in size, but there were no very urgent symptoms at the time of operation. As you see, it is a dual myoma, and in the upper and larger growth there is a considerable cavity which is lined by a zone of calcareous material about one-eighth of an inch in thickness. The cavity was full of mucoid fluid. Bearing on this form of degeneration, I shall presently show on the screen a section from this small myoma, in which is a circumferential area of hyaline degeneration. This, the incipient stage of calcification, is well seen.

This large myomatous tumour illustrates *telangiectatic degeneration*. It was discovered accidentally by a nurse, whose sister complained to her that she had for some time felt a swelling in the abdomen. There had been no special symptom, and the young lady, æt. 39, who was a professional musician, had been following her occupation up to the time of operation. The large cavity contained ten ounces of inodorous, brown fluid—with the *débris* of broken-down necrobiotic tissue. Its walls were soft and covered with soft lymphoid material. A dense fibrous capsule covered the tumour, the core of which was extremely dense and hard.

It was quite superficial, pressing on the abdominal wall, and you can see that only a very thin partition of muscle separated the cavity from the peritoneum. The patient was also a great Alpine climber, and has taken many photographs of glaciers since the tumour was removed.

Multiple Myomata in Mother and Daughter.—I have here an example of a curious coincidence in the matter of myomata. I removed this tumour, the drawing of which, with a description, is in the album. The patient, a multipara, æt. 54, was profoundly anæmic from repeated and profuse hæmorrhages. The risk of operation was great, but with rest and restora-

(a) An Address delivered before the Royal College of Surgeons of Ireland, Nov. 21st. 1912.

tive treatment, she underwent supra-vaginal hysterectomy successfully, and this multiple myoma, weighing five and a-half pounds, and with a large mucoid cavity in its centre, was removed. There were over a hundred nodules of various sizes scattered through its substance. The patient made a permanent recovery. In 1907 I was consulted by her daughter, æt. 33, for menorrhagia, and this multiple myomatous tumour, containing, as you see, a mass of nodules, was removed. She also made an excellent convalescence.

Carcinomatous Invasion of Myoma.—Here is a specimen removed by vaginal hysterectomy from a spinster æt. 58. The tumour was the size of a foetal skull at term. The large intramural fundal fibroid was separated in its capsule from the lower uterine segment, which is also myomatous, and invaded by a soft columnar-celled carcinoma, with solid epithelial branches stretching into it. Below this, in the cervix, is a small benign myoma, and careful examination failed to detect any evidence of malignancy as far as the internal os, though there was inflammatory intramuscular infiltration. The tumour, with the adjacent portion of the vagina, was removed by the vaginal route. She recovered from the operation well, but died some twelve months after from obstruction of the bowel. Though the cause was not ascertained, it was probably of a malignant nature.

Myoma Simulating Pregnancy.—This tumour illustrates the need for caution in diagnosis. A healthy young woman, æt. 38, consulted her doctor for some slight chest symptoms, and, in the examination, the tumour I show was discovered. It reached above the umbilicus, and to the feel, as well as in the appearance of the abdomen, simulated pregnancy. As the breasts were rather large and full, with prominent and dark nipples, and there had been some irregularity of the catamenia, the suspicion of pregnancy was increased, but, fortunately, no question of chastity was raised.

When I saw her, I found the cervix normal, and I was able to dissociate the growth from the uterus. At operation it was found to spring by a pedicle about three inches in width from the left cornu of the uterus. The uterus and adnexa were quite healthy. It was easily removed.

Diffuse Adenoma of the Uterus.—There are two examples of diffuse adenomatous degeneration of the uterus in the collection. One is interesting, as with the uterus are the two ovarian cysts removed by me in previous cœliotomies, with one broad ligament cyst. Subsequent severe hæmorrhage, despite curettage, necessitated hysterectomy, when another broad ligament cyst was discovered. The uterus was entirely adenomatous. Two years after I performed appendicectomy for appendical complications. However, the result of the four cœliotomies was a permanent cure. In the other case there was cystic degeneration of both ovaries, persistent hæmorrhage causing profound anemia, notwithstanding curettage, was the prominent symptom. The operative result was equally satisfactory.

Carcinoma of the Uterus with Fibroma of the Ovary.—This is an interesting specimen showing extensive carcinoma of the cervix uteri, and a large fibromatous tumour the size of a coconut of one ovary. The patient, æt. 56, had passed over the first two years from the cessation of the menopause without any trouble. Then hæmorrhage commenced; this she attributed to the occurrence of the catamenia. It continued at intervals for two years, and she sought no advice. The hæmorrhage then became alarming, and she came to me. The condition disclosed was then discovered. At the operation the ovarian tumour was found isolated. She is in good general health seventeen months after operation, but there is a recurrence in the vaginal vault. The broad ligaments and the adnexa, with the exception of the large ovarian fibroma, are seen to be absolutely free of disease.

Cancerous degeneration limited to the summit of the fundal cavity, in a uterus affected with endometritis, is shown in this specimen. The entire adnexa at both sides with the broad ligaments can be seen to be perfectly normal. By its side is an interesting example

of malignant degeneration occurring in a myoma, and limited to the summit of the tumour.

Pseudo-hermaphroditism and Myoma.—This fœtus illustrating Kleb's pseudo-hermaphroditism has a bearing on myoma uteri and the question of maternal impressions. It was taken at the eighth month from a patient, who was healthy up to the time of her marriage, suffering from mental symptoms and apprehensive delusions. While travelling abroad, she had a shock from the sight of a rather hideous deformed beggar. She became obsessed with the idea that her child would be deformed. It was determined to induce labour at the eighth month. Owing to the growth in the lower segment, it was impossible to deliver by Bossi's dilator or otherwise, so I placed temporary clamps on the vessels, and removed the uterus. I then rapidly extracted from it this monster, which was alive. There is a rudimentary penis with internal female genitalia. Abnormalities are also to be found in the cranium and maxillary bones. The patient's mental symptoms disappeared, and she died well.

Here is a myoma which teaches a clinical lesson. It was removed from a patient who consulted me for an affection of the hip-joint. There had been great pain in the joint for some time, with inability to walk. I discovered the myoma, and at operation this tumour of the ovary was found pressed down on the sciatic by the uterus. The symptoms disappeared on its removal. The Pathological Committee of the Obstetrical Society reported it as a fibro-adenoma of the ovary.

Procidencia.—These two specimens represent extreme cases of procidencia. One is from a patient æt. 74 at the time of operation. The sac which contained the uterus, with the cystocele and rectocele, had been completely protruded from the vulva for over 25 years, all three organs being adherent. In the other, with somewhat similar conditions, the sac was down for over 15 years. In both hysterectomy, with removal of a considerable portion of the vagina, was performed. The bladder and bowel were returned into the pelvis, and the vaginal vault was well secured. In both cases the relief was absolute and permanent. The older patient lived in perfect comfort to the age of eighty-six. The extensive nature of the adhesions to bladder and bowel can be readily seen.

The Adnexa. Giant Scirrhus of the Ovary.—In regard to pathological changes and growths of the adnexa, there is a fairly complete collection. I shall just refer to a few. This scirrhus carcinoma is almost a record specimen. It measures twelve inches in length by twenty-seven in circumference. It was taken from a widow in whom conception might have occurred before her husband's death, and for some time she believed she was pregnant. It grew rapidly, causing no pain, but emaciation, sickness and diarrhoea. After its removal she weighed under six stone. Her other ovary, removed at the same time, is a fair-sized adeno-fibroma. The Fallopian tubes, uterus and meso-salpinx were healthy.

She made a capital recovery, but some five months after operation she died of cancer of the omentum and bowel. She was sent to me by my very old friend, and well-remembered President of this College, the late Edward Dillon Mapother.

Ovarian Sarcoma.—This is a large cysto-sarcoma of the ovary. All the other pelvic viscera were healthy. So far as I know, the recovery was permanent. Here again comes in the difficulty of diagnosis in some of these cases of ovarian solid and semi-solid tumours of the ovary. The growth was thought to be a myoma uteri.

Ovarian Papilloma with Carcinoma of the Uterus.—There is a rare example of carcinoma of the cervix uteri with large papillomatous growths of both ovaries. I was indebted to Dr. Gelston Atkins for the specimen—the original drawing in the atlas. The patient died subsequently to operation from cardiac complications.

Tubo-ovarian Cysts and Abscess.—These examples of ovarian and tubo-ovarian cysts I purposely group together. The first is a large bilocular hæmorrhagic cyst, which I removed entire when it was on the point of rupture, with the opposite diseased adnexa. The Fallopian tube can be seen incorporated with the wall of the cyst, but not communicating with the cavity,

whereas in this large cyst, which I was given by the late Professor John Taylor, the fimbriæ of the Fallopian tube were found on the inside of the cyst wall; the opening can be seen on inspection. Here also is a true tubo-ovarian abscess, and the Fallopian tube is seen opening into the ovarian suppurated sac.

Pyo-salpinx.—There is a specimen of double pyo-salpinx, and the difficulty of operation in this case will be readily recognised from even a slight inspection. The two large pus sacs and the uterus are seen covered by the remains of adhesions. Tubes, ovaries and uterus were matted together in one dense infiltration that filled the pelvis from the level of the crest of one ilium to the other. The bladder was enormously distended, and on the first occasion when I saw the patient I drew off five pints of urine. The summit of the bladder reached to the umbilicus. As many as eight pints of urine were secreted in the twenty-four hours.

My diagnosis was a mistaken one, as I thought I was dealing with a uterine fibroma. Salpingo-oophorectomy with supra-vaginal hysterectomy was performed, and though I had to reopen the abdomen twice after operation, the patient made an excellent and permanent recovery.

Peritoneal Cyst.—There is an unusual condition illustrated by this specimen in which an orange-coloured peritoneal cyst was situated between the sac of a hydro-salpinx and a blood cyst of the ovary. The colour of the peritoneal cyst was bright-orange on its removal, due to absorption from its proximity to the blood cyst.

The Appendix and Adnexa.—This specimen is a good example illustrating the difficulty often found in diagnosis and in differentiating between appendical inflammation, and the tract the infection or inflammation travels by, from the appendix to the adnexa, or from the latter to the appendix. We are greatly indebted to the admirable work done by Dr. Douglas Reid, of Cambridge University, in elucidating the anatomical relations of the appendix to the adnexa. "Studies of the Intestine and Peritoneum in the Human Fœtus," *Journal of Anatomy and Physiology*, 1911-12.

In this specimen we see the appendix, tube, and ovary matted together, while one large concretion, the size of a small bean, blocks the severed appendix, and a second, of the same size, which escaped at operation, is suspended in the fluid. There was no suspicion of an appendical affection until the abdomen was opened.

Ovarian Cystic Degeneration in the Fœtus.—I shall show presently on the screen sections of cystic ovaries given to me when in Heidelberg by Professor Schottlaender. They were taken from a stillborn fœtus. They prove what the late George Carpenter so well showed, that occasionally the foundation of ovarian cystic disease may be laid in fœtal life.

Various Types of Ovarian Degeneration.—There are a number of specimens in the collection illustrative of the various types of cystic, sclerotic, and cirrhotic ovaries; also others showing lutein and hæmorrhagic cysts. I propose later to show with the epidiascope, both macroscopic and microscopic sections of these. They illustrate the ovarian source of dysmenorrhœa. Robert Barnes's term "dysootocia" was a good one. The suffering has often no relation to the size or character of the ovary as it is felt on digital examination. There are also examples of fibroma, fibro-adenoma, and adeno-fibroma.

Dermoids and Malignancy.—The tendency of dermoids to assume a malignant type was shown in the instance of this dermoid cyst. There was no sign of malignancy when it was removed, but the patient died within the year of malignant disease of the omentum.

Pseudo-Adenoma of the Ovary and Malignancy.—In connection with a pseudo-adenomatous ovarian tumour that is in the collection, there is an interesting point connected with the further degeneration of these tumours, and their tendency to become malignant, or the danger of metastasis; also the bearing of the presence of ascites on malignancy. In this case, thirty pints of ascitic fluid were drawn off. There has been no recurrence.

There was a curious histological feature found

on examination of the cyst. The hairs of the cyst wall were being devoured by the multinuclear cells.

Record Ovarian Cyst.—My record ovarian tumour I removed in 1910. The abdominal girth was fifty-eight and a half inches. It was a unilocular cyst of old standing in a woman of 67. There was some ascitic fluid. She made an excellent recovery.

Primary Tuberculosis of the Fallopian Tubes.—I wish to draw your attention to these specimens of primary tuberculosis of the Fallopian tube. The first I show is remarkable as the tuberculous sac was removed from a patient at. 22, who after its removal had four pregnancies, one a twin birth. After her last labour, nine years subsequent to her operation, I had to remove the other adnexa for cystic disease, and the most careful examination failed to discover any tubercle. The microscopical appearances in this specimen and the other three were published in the "Transactions of the Royal Society of Medicine." So far as I know, all four women are in good health at present.

Ectopic Gestation.—I shall only ask your attention to four instances of ectopic gestation included in the collection. One is a very early ovum of about the eighth day, the earliest I have seen. There is a rupture visible in the sac, and the pelvis was full of blood when I operated. The patient did well. The second shows a large suppurative cavity in the wall of the sac which contains the fœtus. It had lain for a long time in Douglas's pouch, having been mistaken for an enlarged retroverted uterus. The contents of the outer sac were putrid; some escaped and infected the parietal wound. The patient died of the wound infection, for the pelvic and abdominal cavities were found to be quite healthy when the abdomen was re-opened. This taught me a lesson, for not long after I had a case of ruptured pericæcal abscess with a sloughed appendix. After cauterising and protecting the stump of the latter, and thoroughly cleaning the peritoneal cavity with swabs wrung out of weak formalin, and shutting off the bowel, I resected the edges of the abdominal wound through its entire length, brought the vivified layers together, put in a supra-pubic drain, and the patient is a healthy woman to-day. I should not in all probability have lost the first had the edges of my wound been properly covered and protected at operation. Time teaches us much. The only other ectopic case I have lost you see in this specimen. The abdomen was full of blood; there was a large rent in the broad ligament; blood was issuing from this and from the placenta, which, with the sac, was in the abdomen adherent to the bowel. The fetus had escaped into the abdominal cavity and was found under the spleen. The bleeding was completely arrested, but the patient died from the shock and hæmorrhage.

There is a specimen of peri-tubal hæmatocele, showing what is rather an unusual feature, viz., the incorporation of the ovary with the gestation sac spread out on its posterior surface. This was only discovered by Dr. Lockyer on making a section of the wall. This cyst of the meso-salpinx exhibits the difficulty in diagnosis in some cases of ectopic gestation. The usual symptoms indicative of gestation were present. It proved to be a parovarian cyst which had ruptured.

Primary Carcinoma of the Fallopian Tube.—There is one specimen of primary carcinoma of the Fallopian tube which, as you are aware, is very rarely met with. It was reported on by Dr. Lockyer, and is fully described in my manual of "Diseases of Women," in which a full macroscopical and microscopical report appears. It was unilateral. Unfortunately, the tumour was laid aside, and was not discovered for some time, so I could not trace the clinical particulars of the case.

Omega Tube.—Here is seen a curious consequence of chronic salpingo-oophoritis. The right tube is doubled on itself into an omega-shaped mass, with a cystic ovary attached, and the meso-salpinx is absent. The adnexa of the left side were pathologically affected in a similar manner. Both adnexa were buried in a parametric infiltration, and the operation was a difficult one. But the patient made an excellent recovery.

Syphilitic Salpingitis.—I should like to ask your inspection of these tubes. I have never seen anything

quite like them. The dense, round-celled infiltration invading all the walls of the tubes, filling their lumen, and the greatly hypertrophied vessels, give their sections a sort of foliaceous appearance. The tubes were taken from a young patient who was perfectly healthy before she contracted syphilis. During the desquamative stage, she first complained of adnexal pain. The same year I saw her, and removed the tubes.

Accessory Hydro-salpinx.—There are several specimens here, one of which was specially reported on for me by Mr. Sampson Handley, illustrative of the condition so well described by him of accessory Fallopian tubes, or accessory hydro-salpinx. These cysts are above the broad ligament, some open into the tubes. One specimen, he says, is of importance, as proving that certain cysts of the broad ligament are of Mullerian origin. The cysts histologically partake of the characters of the Fallopian tube.

Vaginal Cysts.—Much has been written on the ætiology of vaginal cysts, and the work of Santi abroad and Roger Williams at home is well known. There is an interesting example in the collection of a vaginal cyst which I removed in 1905 from a patient æt. 35 years. A few months previous to its removal during an operation for curettage, I discovered in the vaginal vault a cystic tumour the size of a pigeon's egg. Dr. Lockyer, who examined both specimens, reported that its epithelial lining was of the spherical type. This cyst, which I removed later, must then have been concealed from view by the vaginal speculum during the operation. I dissected it out in its entirety from its surrounding of fibro-muscular tissue, and its waxy lining contained cubical epithelium. It is for pathologists to say what was the origin of the upper cyst and whether the lower one was of a Gärtnerian or Wolffian nature.

Primary Carcinoma of the Kidney and Angioma of the Liver.—There are two interesting specimens, not gynecological, one of primary carcinoma of the kidney, and another of angioma of the liver. The first patient lived for two years after I removed the kidney. There was recurrence in the cicatricial tissue of the wound. The second died from the shock of the operation.

Ganglion Neuroma of the Mesentery.—My last contribution to the Museum includes this specimen of ganglion neuroma (partly embryonic) of the mesentery. Complete drawings of the microscopical features of the tumour, and the various sections prepared by Dr. Turnbull, of the Pathological Institute of the London Hospital, accompany it. His pathological report of this unique specimen is one of the most exhaustive I have ever received.

I shall not delay to refer to any other specimens, but proceed to refer to some of the microscopical specimens which form part of the collection. [The microscopical demonstration included sections illustrating the pathology of the various specimens which had been referred to. In addition to these were several others, including metastasis from the mammary gland to the spinal cord, with carcinomatous tumour of the latter; fibroma of the mammary gland degenerating into sarcoma; primary tuberculosis of the mammary gland; various pathological changes in the Fallopian tube; carcinoma of all the internal genitalia with the exception of one Fallopian tube—the muscular tunic only of the bladder being involved; cancerous degeneration of a uterine polypus; hydatidiform mole; various pathological conditions of the ovaries and malignant disease of the vagina and vulva.]

OPERATING THEATRES.

BOLINGBROKE HOSPITAL.

PREPATELLAR BURSA.—MR. SWAINSON operated on a man, æt. 30, who had for a year been the subject of a prepatellar bursa; this was probably caused by his occupation, in which he was accustomed to kneel a good deal, bearing his weight on the right knee. The diagnosis was obvious: a large, tense, fluctuating swelling being situated in front of the patella. There

were no signs of inflammation, and it was decided to remove the bursa.

A semilunar incision, convex outwards, was made on the outer side of the swelling, and the skin raised by careful dissection from the bursa. A few vessels were ligatured, then the bursa was dissected off the patella. The skin flap was replaced and the wound sewn up. The knee was firmly bandaged with a roll of gauze so as to apply pressure; wool and a bandage were applied over all.

Mr. Swainson said this was a very simple case, but none the less interesting. He would call attention to the fact that the condition was much more common in women than in men. As to the operation, it would be noticed that the incision was made on the outer side and not in front of the knee-joint, so that the subsequent scar would not be exposed to pressure. Care was taken not to buttonhole the skin, and not to wound the knee-joint. There was little more to say as to the case itself, but he would now refer to some of the diseases of bursæ in general and to adventitious bursæ. As to diseases, acute, simple bursitis might arise from injury, and could be treated by rest, application of heat, and if necessary, by aspiration. Simple bursitis might pass on to an infective bursitis, which might also be caused by wounds. Incision and drainage would here be necessary. The condition which he had operated on, usually known as housemaid's knee, might be regarded as a chronic simple bursitis due to a chronic injury. Similar bursæ to the prepatellar bursa sometimes occur in other situations, as over the acromion process in Chinese coolies and in persons who carry timber. Over the ischial tuberosity a similar bursa sometimes occurs in weavers. A fibroid or plastic bursitis sometimes occurs in which there is little or no serous fluid. Tuberculous, syphilitic and malignant disease could also occur. Diagnosis of malignant disease was not always obvious. Mr. Swainson said he had seen a fibrous bursa cut out which under microscopical examination proved to be sarcoma.

As to the subsequent history of the patient operated on, the wound was healed in a week.

VARICOSE VEINS.—The same surgeon operated on a case of varicose veins in a man. There was a mass of veins below and internal to the knee. The internal saphenous vein was exposed by a transverse incision in the middle of the thigh and about an inch of the vein cut out. The vein was ligatured in two places and the wound sewn up. Next an oblique incision about nine inches long was made over the mass of varicose veins; the edges of the wound were dissected up for a short distance, and the mass of veins removed by dissection, the deep fascia being exposed. The second wound was then sewn up and a dressing firmly applied.

Mr. Swainson said that in this case, as the veins were fairly localised, it was sufficient to remove them completely, and also to tie the saphenous vein, as had been done. In cases where the varicose veins were more extensive, he pointed out that it has been recommended to make an oblique spiral incision encircling the limb and to remove all the veins thus exposed so as to more completely interrupt the circulation. This method, he thought, gave good results in cases where the veins were extensive. As to the causation of varicose veins, Mr. Swainson said that congenital and mechanical theories had been propounded, both of which seemed reasonable. Secondary varicosity of superficial veins could also be caused by thrombosis of the deep veins. The complications of varicose veins were: rupture, in which severe bleeding might occur, but which elevation and pressure would stop; phlebitis, which was an important complication, and could be treated by rest, and in some cases by ligature of the vein on the proximal side; and embolism, which was a rare complication.

ACCORDING to a message from Sydney 20 deaths from plague have occurred lately in one hospital at Noumea, New Caledonia, and the outbreak is disorganising business.

TRANSACTIONS OF SOCIETIES.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD (IN THE STAFFORD ROOMS), THURSDAY,
NOVEMBER 21ST.

The President, Dr. H. J. MACEVOY, in the Chair.

DR. GOSSAGE read a paper on
HEREDITY.

He pointed out that the subject of heredity was inextricably mixed up with that of evolution, and discussed the three chief theories of evolution—that of Lamarck, that of Darwin, and the Mutation theory. The evidence in favour of any of these was founded on the study of animals and plants, but they could be illustrated from human beings. Human evidence was, however, insufficient to establish any point. Lamarckism, or the inheritance of acquired characters, must be regarded as disproved by the work of Weismann. Between the other two theories it was at present impossible to decide. Darwinism failed to convince from the lack of conclusive evidence of evolution by the selection of fluctuating variations, while there were many difficulties to overcome and apparent exceptions to be explained before the Mutation theory and Mendelism could be definitely accepted.

Mr. CAMPBELL WILLIAMS and Dr. GRAHAM LITTLE discussed the paper, and Dr. Gossage replied.

Mr. W. H. CLAYTON-GREENE then read a paper on some

BACTERIAL INFECTIONS OF THE URINARY TRACT.

Mr. D. C. L. FITZWILLIAMS, Mr. CAMPBELL WILLIAMS, Dr. SYDNEY PHILLIPS, and Dr. GRAHAM LITTLE discussed the paper, and Mr. Clayton-Greene replied.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, NOVEMBER 21ST, 1912.

The President, Sir ROBERT JONES, in the Chair.

DR. ARTHUR WALLACE read a note on the
CONTROL OF THE CONVULSION IN ECLAMPSIA.

Dr. Wallace quoted the statistics of Stroganof, who in 400 cases lost 6.6 per cent. mothers and 21 per cent. of children, these cases being treated in hospital with the fits controlled by morphia, chloral, or chloroform. He alluded to the observations of Dienst on the thromboses due to the unusual coagulability of the blood, and Englemann's suggestion that leech extract might be used to diminish the coagulation, and, therefore, the thromboses. He then alluded to Dr. Leith Murray's suggestion that injections of magnesium sulphate solution into the spinal canal might be useful in eclampsia, as it had been found useful in tetanus. Dr. Wallace had employed a 25 per cent. solution of magnesium sulphate in a dose of, approximately, 1 c.c. of solution for every 25 lbs. of body weight.

The first case, a woman *æt.* 30, in her third labour, had had eight fits. 4 c.c. of the solution were injected into the spinal canal, and there were no more fits for seven hours. Spontaneous delivery occurred five hours after the last fit, a live child was born, and a slight convulsion occurred three-quarters of an hour after; the patient was unconscious for some hours after, but made a good recovery.

The second case was a primipara. She had had six well-marked fits. The injection was given, with no fit for four hours. A second injection was given, as the attacks had recurred. There was spontaneous delivery and ultimately recovery.

Dr. LEITH MURRAY, in discussing the note, spoke of the frequency with which cerebral hæmorrhage was found to be the cause of death. He did not think harm could be done by the injection of magnesium sulphate solution, as it would be a simple matter if there was any embarrassment of respiration to wash out the spinal canal with an isotonic solution.

Dr. LLOYD ROBERTS read a short paper on the

EARLY SYMPTOMS OF MEDIASTINAL TUMOURS.

He had treated recently 36 cases. The symptoms were due to the pressure on adjacent structures. Dr. Roberts especially drew attention to the symptoms of venous obstruction, and more particularly to pressure on the large azygos vein. When that was pressed on, as in a case of mediastino-pericarditis, there was general anasarca of the body, with effusion into the peritoneal and pleural cavities, but with no abnormality of the urine. The heart in these cases was normal, the beat slow and regular, no murmur, the symptoms being due to pressure on the superior vena cava and right auricle. Where the azygos vein was pressed on in the upper part of its course, there was serous effusion mostly in the abdominal walls, loins, and lower limbs, and no proportional peritoneal effusion. In most cases the effusion was bi-lateral, but in some cases uni-lateral, and then the pressure could be located to the region below the 9th dorsal vertebra, where the veins of the two sides joined.

Respiratory obstruction was a frequent early symptom, which might be found alone or more usually with venous obstruction. As had been pointed out by Dr. Glynn, there was in these cases marked alteration in vocal fremitus. Dyspnoea on exertion was a usual symptom, but was seen, especially in cases of gumata, out of proportion to the size of the growth.

Pressure on nerves gave rise to early symptoms; pressure on the intercostals gave pain in the back and sides, and was mistaken for pleuritic pain. Pressure on the phrenic in some cases had given rise to pain in the shoulder, through the communication with the superior acromial nerve. Pressure on the sympathetic gave rise to unequal pupils. Pressure on the vagus gave laryngeal paralysis and alterations in pulse rate, and in occasional cases to dysphagia, vomiting, or hiccough.

Dr. T. R. GLYNN congratulated Dr. Lloyd Roberts, and spoke of the value of the alteration in vocal fremitus in diagnosing these tumours. Dr. Glynn had found involvement of the spinal cord not infrequent in mediastinal tumours, and in one case paraplegia had been the first sign of a growth.

Dr. JOHN HAY alluded to the infrequency of general symptoms and cachexia in malignant disease of the root of the lung.

Dr. W. PERMEWAN said that among the earliest symptoms, he had noted a paralysis of the vocal cords on one side only, which did not cause any alteration of the voice. He thought that paralysis of the cords was more frequently seen in aneurysm cases than in cases of malignant growth. A left-sided paralysis with no obvious cause was, in 90 per cent. of cases, due to aneurysm. Malignant disease of the œsophagus frequently gave rise to paralysis on both sides of the larynx as an early symptom.

Dr. O. T. WILLIAMS alluded to a case where a tumour which had given rise to pain, and a shadow in X-ray photograph, had disappeared under treatment, but had recurred, with a fatal result, within three years.

Dr. R. M. BUCHANAN said that effusion into the pleura never gave the same complete absence of fremitus that an obstructed bronchus gave. He had found an ineffective and irritative cough often an early symptom.

Dr. W. WARRINGTON and Dr. E. T. DAVIES also spoke. Dr. LLOYD ROBERTS replied.

Dr. FRANCIS BAILEY opened a discussion on

THE TECHNIQUE OF ETHER ADMINISTRATION.

The first part of his remarks was devoted to the history of the use of ether. He then showed a variety of apparatus that had been used, from an early inhaler of Snow's to Kelly's intratracheal insufflation apparatus and Roux's apparatus for intravenous injection of ether. Dr. Bailey detailed the preparation of the patient, and discussed the use of atropine, morphia, etc. He thought they were of use in moderate doses, and given a half to three-quarters of an hour before the anæsthetic. He used a Skinner's mask covered with stockingette, a drop bottle, a ring pad round the mouth, and several layers of gauze to cover the mask. The patient was asked to breathe

quietly by the mouth. As little movement as possible should be made once the anaesthesia was begun. There should be good colour and even respiration throughout, the airways should always be kept patent, the jaw could be kept forward by a finger behind the angle, and the lips open in edentulous people by the thumb in the mouth. It took six minutes to anaesthetise the average patient, using $1\frac{1}{2}$ to 2 oz. of ether. Eight to 10 oz. were required for an operation lasting an hour. Patients did best with an 8 per cent. vapour. Dr. Bailey described the *technique* of intratracheal insufflation and of the intravenous method.

In the discussion that followed, Mr. R. Kelly described the experiments of Henderson, of Connecticut, who had in the laboratory reproduced all the errors of unskilful administration of anaesthetics, and so demonstrated the causes of fatalities which are ascribed to status lymphaticus, enlarged thymus gland, etc. Respiratory failure was the commoner of the two, cardiac failure accounting for the lesser proportion of cases. The real cause of the fatal failure of respiration was deep breathing and intermittent anaesthesia; the normal stimulus to the respiratory centre being the presence of carbonic acid in the blood of the centre; with over-deep breathing the carbonic acid was not present in sufficient quantity to keep the centre active. Cardiac failure was due to prolongation of the struggling stage or to pain during the intermittence of administration. Mr. Kelly advised that anaesthetics should not be mixed, and that no operation should be done under partial anaesthesia. In respiratory failure artificial respiration should be performed, and in cardiac failure massage of the heart. He had used intratracheal insufflation in 70 cases, and was quite satisfied with its action. Ether pneumonia was not due to the ether, but to septic saliva being present in the bronchi.

Mr. Thelwall Thomas laid it down as a primary rule that anaesthetics should not be mixed. He had seen as many as seventeen cases die from chloroform, and considered ether much the safest general anaesthetic. We had been brought to this opinion by the superior results obtained in America in cases of septic peritonitis, our cases did equally well when ether was the anaesthetic used. Ether should be administered without any closed bag by the open method, as Dr. Bailey had described. Atropine certainly diminished the secretions, but he did not think it was of great advantage; he rather thought cases of parotitis might be due to the arrested secretion. He thought the intratracheal method had a field of usefulness in cases where respiratory movements interfered with the operation, as in difficult gall-bladder cases, and in mediastinal and tracheal work.

Dr. BAILEY shortly replied.

SPECIAL REPORTS.

GENERAL MEDICAL COUNCIL.

NINETY-SIXTH SESSION.

TUESDAY, NOVEMBER 26TH, 1912.

The President, SIR DONALD MACALISTER, in the Chair.

THE PRESIDENT announced that he regretted to inform the Council that Dr. Gibson (Edinburgh) would be unable to be present on account of the state of his health. The President was pleased, however, to be able to say that Dr. Gibson was convalescent.

The official notification of the appointment of George Wilks, M.B., as Representative of the Society of Apothecaries, London, for one year from October 22nd, 1912, was read. Mr. Wilks was introduced by Dr. Norman Moore. Also that of John Christie McVail, M.D., as Crown Nominee for Scotland for five years, from October 28th, 1912. Dr. McVail was introduced by Dr. Norman Walker.

THE PRESIDENTIAL ADDRESS.

The PRESIDENT then delivered the following address:—

GENTLEMEN,—It falls to me once more to record changes in the membership of the Council. During the summer we lost by death our colleague, Mr. Arthur Trehern Norton, C.B., who since February, 1910, had represented the Society of Apothecaries of London. Though his period of office was short, it was long enough to procure him the regard of the Council, which did not fail to appreciate his diligent attention to business, and his soldierly courtesy of bearing. In his place we welcome Mr. George Wilks, formerly Master of the Apothecaries' Society.

On Saturday we received from the Privy Council an official notification of the appointment by His Majesty of Dr. J. C. McVail as the Crown member for Scotland, in the room of his brother, Sir David C. McVail, whose fourth term of office has just expired.

In Dr. John McVail we acquire a member of high eminence and wide experience in relation to departments of the public medical service, of which from time to time the Council has of necessity to take cognisance. . . . As Vice-Chairman of the National Insurance Commission for Scotland, Dr. McVail will have it in his power to make contributions of value to the Council's discussions of a new and extremely important branch of State Medicine. . . .

The Council will learn with regret of the death of Dr. Cocking, of Sheffield, who represented the University of that city from 1905 to 1911. The published tributes to his character and services have amply confirmed the impression left upon the Council by his memory.

The Government of Ireland Bill and the Medical Acts.—In accordance with the resolution of the Council, passed *nemine contradicente* on June 4th, I communicated to the Lord President your desire that steps should be taken to procure the insertion, in the Government of Ireland Bill, of provisions reserving to the Imperial Parliament the control of legislation relating to the Medical and Dentists Acts. At the request of the Government I prepared a memorandum setting forth the general grounds on which the Council's resolution was commended to the favourable consideration of Parliament. . . . Notices by private members, proposing amendments to the Government of Ireland Bill in the general sense of your resolution, have appeared on the Order-paper of the House of Commons; but under the procedure adopted by the House they have not come up for discussion. The importance of the subject, especially in its bearing on the continued validity, for registration purposes, of qualifications granted in Ireland, appears to have impressed itself on non-official members of Parliament, and there is some ground for the expectation that, during the stage of "Report," an opportunity will be found for its consideration.

The National Insurance Act, and the rules and regulations proposed to be made thereunder, have received the careful attention of your Special Committee. . . . Through the Privy Council an early draft of the Provisional Regulations for Medical Benefit was submitted for criticism by the Committee in September last. The Committee's terms of reference appeared at first sight to limit its consideration to the effects of the Provisional Regulations "on Medical Education and Examination in relation to the efficient practice of Medicine"; but the members deemed it their duty to direct the Commissioners' attention to various other points concerning which on previous occasions the Council had formulated resolutions. In particular, the Committee reiterated the opinion of the Council to the effect that, in the absence of any sufficient provision for the "institutional" treatment of insured persons, the existing facilities for the study of clinical medicine, surgery, and midwifery, might be seriously endangered; and that the efficiency of medical education, and consequently of medical practice among all sections of the public, might thereby be impaired. The Insurance Commissioners have informed the Lord President that the Committee's suggestions were found to be exceedingly useful and valuable; and that, apart from the question of hospital facilities, which the Commissioners appear to regard as outside the present Act, effect was given to these suggestions in the Provisional Regulations as

issued. It is understood that the Regulations are still subject to modification, and that negotiations to this end are now in progress. . . .

Amendment of the Medical Act.—In response to suggestions from the Council, the Lord President has prepared, and introduced into the House of Lords, a Bill for amending in a few particulars Section 8 of the Medical Act, 1886. This section governs the dates prescribed under the regulations for the election of Direct Representatives to the Council. . . . The Bill provides that the tenure of office of the present Representatives shall extend to the end of 1916, in order that the next five-years period shall begin on the first day of January, 1917. The special thanks of the Council are due to the Lord President for his effective assistance in furthering this simple but necessary administrative reform.

Registration in Canada—It is with much satisfaction that I report the completion in Canada of the legislation necessary to provide for the establishment of a federal Medical Council and a uniform system of registration for the Dominion. . . . The organisation of the first Dominion Medical Council has been entrusted to the Secretary of State at Ottawa, who is himself a medical man. At his request our Registrar has forwarded to the new body, for its guidance, a set of the Council's publications, forms, regulations, etc. Dr. T. G. Roddick, of Montreal, to whose patient labours is due the achievement of Canadian inter-provincial reciprocity through Dominion registration, has kindly promised to keep the Council informed of the future progress of the scheme.

I have also to report the completion by Mr. Harper, Solicitor to the Council, of an important volume containing an account of all the cases dealt with by the Higher Courts of Law, in which questions of the interpretation of the Medical and Dentists Acts have been raised. . . .

By your instructions the recent report on Indian candidates for professional examinations in this country was sent to all qualifying bodies and medical schools.

The Education Committee has made considerable progress with the revision of the list of recognised Preliminary Examinations held outside the United Kingdom, regarding which it has been in correspondence with the various educational authorities of the Empire. . . .

The Pharmacopœia Committee has, with the help of its editors, been engaged in preparing for press the draft of four large sections of the text of the revised *Pharmacopœia*. . . .

The Treasurers and the Registrar have instituted an inquiry into the existing methods of preparing and printing the matter contained in the *Medical Register* and the *Dentists' Register*, with a view to its clearer and more convenient presentation. . . .

Much of your time this Session will be occupied with the consideration of penal charges. . . . In this connection it is proper to record that the Home Secretary has now, at the request of the Penal Cases Committee, issued instructions to the police authorities throughout England to notify the Council of all cases in which medical or dental practitioners are convicted, whether of indictable or of other offences. . . .

Personation.—Lastly, I must call your attention to a special inquiry to be held on Thursday, for which there is no strict precedent on the medical side of our proceedings. In this case there is no "accused practitioner," as the inquiry relates to the continued appearance in the *Medical Register* of the name of a practitioner alleged to have died abroad some years ago. It is further alleged that some one, who is unqualified and therefore not subject to your jurisdiction, has been personating the deceased practitioner and practising medicine under his registered name and qualifications. If these allegations are proved, the entry in the *Register* must be erased by your direction; and the charge of personation will then have to be investigated by the criminal authorities. . . .

On the conclusion of the President's address, it was moved by Dr. LITTLE, seconded by Dr. NORMAN MOORE, and carried by acclamation:—"That the

President be thanked for his address, and requested to let it be printed in the Minutes."

It was then moved by Dr. NORMAN MOORE, seconded by Sir JOHN MOORE, and agreed to:—"That the thanks of the Council be conveyed to the Director-General of the Medical Department of the Royal Navy, the Director-General of the Medical Department of the Army, and the Under-Secretary of State for India, respectively, for the returns which they have again furnished to the Council, with the request that such returns may in the future continue to be furnished to the General Medical Council."

The Report by the National Insurance Act Committee in regard to representations sent to the National Health Insurance Joint Committee as to:—

- (1) The possible effect of the Act on the education of students in midwifery;
- (2) The Draft Regulations for the administration of medical benefit

was also received and entered on the Minutes, as well as the Report by the Executive Committee with reference to the calling in of doctors by midwives.

The Committee recommended the General Council to transmit to the Privy Council an expression of its strong disapproval of Clause 2 of the "Conditions affecting the practice of Midwifery in the Borough of Chesterfield" contained in the circular which has been forwarded.

The Clause reads as follows:—

"2. Doctors will not attend emergency notes from midwives requiring medical help, unless the patient has previously retained a doctor in case his services are required."

Moved by Dr. NORMAN MOORE, seconded by Sir HENRY MORRIS, and agreed to:—"That the recommendations contained in the report of the Executive Committee be adopted."

On strangers being re-admitted, after the Council had deliberated *in camera*, the PRESIDENT announced that the Registrar had been directed to restore to the *Medical Register* the name of David Thomas Jones, and to the *Dentists' Register* the name of Thomas Wafer Byrne.

The PRESIDENT also announced that as the result of the ballot Dr. Norman Walker had been elected a member of the Executive Committee for Scotland.

The Council then adjourned.

SECOND DAY—WEDNESDAY, NOVEMBER 27TH, 1912.

The President, SIR DONALD MACALISTER, in the Chair.

CASES OF ALLEGED UNPROFESSIONAL CONDUCT.

The Minutes of the last meeting were taken as read and, as amended, confirmed.

The Council proceeded to the consideration, adjourned from Friday, June 7th, 1912, of the case of Darabshaw Fardoonji Sanjana, formerly registered as of the Hampden Residential Club, London, but now as of Sanjan House, Kelty, Fife, L.R.C.P. Edin., L.R.C.S. Edin., L.F.P.S. Glasg. 1901.

The complainants were the British Medical Association.

At the conclusion of the proceedings on June 7th, 1912, the following decision of the Council was announced by the President:—"Mr. Sanjana: I have to inform you that the Council have deliberated on your case, and have found that certain of the facts alleged against you in the Notice of Inquiry have been proved to their satisfaction. . . .

"The Council take a serious view of the particular facts found to be proved against you; but in order to give you an opportunity of showing that your professional conduct is henceforth to be without reproach, they have postponed judgment on the facts as found until the November session of the Council. At that session you will be required to attend, and you shall then produce evidence regarding your professional conduct, testified to by medical practitioners and other persons of position who may be acquainted with your practice and conduct in the interval."

Mr. Sanjana attended in answer to his notice, accompanied by Mr. James Currie Macbeth, of Messrs. Macbeth, MacLain and Currie, of Dunfermline, his solicitor.

The British Medical Association, the complainants, were represented by Mr. Alfred Cox, their general secretary.

The PRESIDENT intimated that, as the complainants in this case were the British Medical Association, members of the Council who were members of that body should take no part in the consideration of this case.

Dr. Macdonald, Mr. Wilks, Dr. McVail, Mr. Verrall, Dr. Kidd, and Dr. Lorrain Smith accordingly withdrew.

Owing to a misunderstanding of the Standing Orders, Mr. Sanjana had not lodged the required evidence seventeen days before the date fixed for the resumed hearing. Mr. Macbeth therefore sought leave under Standing Order xiv., 16, to put in certain declarations. Leave was accorded.

Mr. Macbeth then read statutory declarations by Mr. James Terris, J.P., factor of the Blairadam Estate, near Kelty; Mr. Archibald Adam, J.P., of Kelty; the Rev. Alexander Shaw Adamson, minister of the Moray United Free Church, Kelty, and Mr. William Adamson, M.P. for West Fife, as to the character of Mr. Sanjana during the period of probation.

He called Mr. Sanjana as a witness. Mr. Sanjana answered questions put to him by the Legal Assessor, and from the Chair; also a question put to him by a member of the Council through the Chair.

After Mr. ALFRED COX had addressed the Council on behalf of the complainants, strangers withdrew, and the Council deliberated *in camera*.

On strangers being readmitted, the PRESIDENT announced the decision of the Council as follows:—"Mr. Sanjana: I have to inform you that the Council has not seen fit to direct the Registrar to erase your name from the *Medical Register*."

The Council proceeded to the consideration adjourned from Friday, June 7th, 1912, of the case of John Jeeves, registered as of 163 Cemetery Road, Sheffield, M.R.C.S.Eng. 1889, L.R.C.P.Lond. 1889.

The complainants were the British Dental Association.

At the conclusion of the proceedings on June 7th, 1912, the following decision of the Council was announced by the PRESIDENT. Addressing Mr. Jeeves, he said: "I have to inform you that the Council have found that the facts alleged against you have been proved to their satisfaction. The Council are of opinion that it is the duty of a registered medical practitioner to ascertain that an operator is a duly registered medical practitioner or dentist before administering anæsthetics for him. The Council take a very grave view of the action of practitioners who administer anæsthetics for unregistered persons. They have, however, postponed judgment on your case till the November session, when you will be required to produce evidence, satisfactory to the Council, as to your professional conduct in the interval."

Mr. Jeeves attended in answer to his notice. He was not accompanied by counsel or solicitor.

The British Dental Association, the complainants, were represented by Mr. R. W. Turner, counsel, instructed by Messrs. Bowman and Curtis-Hayward, solicitors.

Mr. Jeeves read testimonials as to his character during the period of probation from Dr. Robert B. Greaves, Dr. E. B. Hazleton, and Mr. W. W. Bamham, M.R.C.S., L.R.C.P., medical practitioners, of Sheffield.

He answered questions put to him from the Chair and by Mr. R. W. Turner on behalf of the complainants.

Strangers having been readmitted, after the Council had deliberated *in camera*, the PRESIDENT announced the decision of the Council as follows:—

"Mr. Jeeves: I have to inform you that the Council has not seen fit to direct the Registrar to erase your name from the *Medical Register*."

The Council proceeded to the consideration, adjourned from June 5th, 1912, of the further report of

the Dental Committee on the case of William John Watson, registered as of 8 New Street, Birmingham, in practice before July 22nd, 1878.

At the conclusion of the proceedings on June 5th, the following decision of the Council was announced by the PRESIDENT to counsel for the complainants, the British Dental Association:—

"Mr. Turner: I have to announce that the report of the Dental Committee has been referred back to it for further inquiry and report."

Mr. Watson did not attend in answer to his notice, nor was he represented by counsel or solicitor.

The British Dental Association, the complainants, were represented by Mr. R. W. Turner, counsel, instructed by Messrs. Bowman and Curtis-Hayward, solicitors.

The Registrar read the further report of the Dental Committee.

Mr. Turner did not seek leave to address the Council on the report.

Strangers having been readmitted, after the Council had deliberated *in camera*, the PRESIDENT announced the judgment of the Council as follows:—

"Mr. Turner, in Mr. Watson's absence, I have to inform you that the Council does not see fit to direct the Registrar to erase from the *Dentists' Register* the name of Mr. William John Watson."

The Council proceeded to the consideration of the Report of the Dental Committee on the case of George William Thomas Arrowsmith, registered as of Whitstable, Kent, in practice before July 22nd, 1878, who had been summoned to appear before the Committee on the following charge:—"That being a registered dentist you have permitted an unqualified person named F—— J—— Oaten to practise in your name or in partnership with or as assistant to you as a dentist at Westcliff House, Oxford Street, Whitstable, and that you have thereby enabled him to practise as if he were qualified. And that in relation thereto you have been guilty of infamous or disgraceful conduct in a professional respect."

The complainants were the British Dental Association.

Mr. Arrowsmith did not attend in answer to his notice, nor was he represented by counsel or solicitor.

The British Dental Association, the complainants, were represented by Mr. R. W. Turner, counsel, instructed by Messrs. Bowman and Curtis-Hayward, solicitors.

The Registrar read the notice and the report of the Dental Committee, and Mr. R. W. Turner addressed the Council as to the facts.

Strangers having been readmitted, after the Council had deliberated *in camera*, the PRESIDENT announced the judgment of the Council as follows:—

"Mr. Turner: In the absence of Mr. Arrowsmith I have to inform you that, on the facts found in the report of the Dental Committee, it has been proved that George William Thomas Arrowsmith has been guilty of infamous or disgraceful conduct in a professional respect, and that the Registrar has been directed to erase from the *Dentists' Register* the name of George William Thomas Arrowsmith."

The Council proceeded to the consideration of the case of Alfred Arthur Austin, registered as of 86 Sherlock Street, Birmingham, L.A.H.Dubl. 1887, L.R.C.S.Irel. 1887, who had been summoned to appear before the Council on the following charge:—

"That, being a registered medical practitioner, you were on July 10th, 1912, convicted at the Birmingham Assizes of feloniously killing and slaying one Lena Kimmond, and sentenced to seven years' penal servitude."

Mr. Austin was not represented by counsel or solicitor.

The Registrar having read the notice, the Council's solicitor, in the absence of a complainant, laid the facts before the Council. He read the certificate of conviction, and extracts from the transcript of the shorthand writer's notes.

This closed the case.

Strangers having been readmitted, after the Council had deliberated *in camera*, the PRESIDENT announced the judgment of the Council as follows:—"Mr.

Harper : I have to announce that the Council has come to the following decision :—

"That Alfred Arthur Austin, having been proved to have been convicted of the felony alleged against him in the Notice of Enquiry, the Registrar has been directed to erase from the *Medical Register* the name of Alfred Arthur Austin."

The Council proceeded to the consideration of the case of Herbert Alfred de Pinna, registered as of 20 Grosvenor Street, W., M.R.C.S.Eng., L.R.C.P.Lond. 1905, who had been summoned to appear before the Council on the following charge :—

"That, being a registered medical practitioner, you were on May 1st, 1912, convicted at the Chertsey Petty Sessions of the following misdemeanour, namely, of exposing your person, and were sentenced to six weeks' imprisonment in the second division, which sentence was on July 2nd, 1912, on appeal by you to the Surrey Quarter Sessions, altered to a fine of £50, and you were ordered to pay the costs of the appeal."

Mr. de Pinna did not attend in answer to his notice, but was represented by Mr. Elvey Robb, solicitor.

The Registrar having read the notice, the Council's solicitor, in the absence of a complainant, laid the facts before the Council. He read the certificate of conviction, and the judgment of the Surrey Quarter Sessions.

Mr. Robb addressed the Council on behalf of Mr. de Pinna, who was abroad at the time that the summons was issued, and asked that the case might be adjourned for six months in order that he might bring forward evidence as to Mr. de Pinna's state of mind at the time that the offence was committed, and as to the state of his general health.

He answered questions put to him by Mr. Bodkin in regard to the case.

Mr. Harper addressed the Council in reply. Mr. Robb answered further questions put to him through the Legal Assessor and by members of the Council.

Strangers having been readmitted, after the Council had deliberated *in camera*, the PRESIDENT announced the decision of the Council as follows :—

"Mr. Robb : I have to inform you that the Council has found the conviction for misdemeanour proved against Mr. de Pinna, but that judgment has been postponed until the next session of the Council in May."

The Council proceeded to the consideration of the case of William Arnold Thomson, registered as of Castle Hill, Maidenhead, L., L.M. 1869, K.Q.C.P. Irel., L., 1869, F. 1874, R.C.S.Irel., who had been summoned to appear before the Council on the following charge :—"That, being a registered medical practitioner, you were on May 14th, 1912, convicted at the Central Criminal Court of feloniously and unlawfully using an instrument with intent to procure miscarriage, and sentenced to three years' penal servitude."

Mr. Thomson was not represented by counsel or solicitor.

The Registrar having read the notice, the Council's solicitor laid the facts of the case before the Council. He read the certificate of conviction, a letter from Mrs. Thomson, dated November 5th, 1912, extracts from the depositions taken at the hearing of the case, and from *The People* newspaper, of May 19th, 1912.

This closed the case.

Strangers having been readmitted, after the Council had deliberated *in camera*, the PRESIDENT announced the judgment of the Council as follows :—"I have to announce that William Arnold Thomson, having been proved to have been convicted of the felony alleged against him in the Notice of Inquiry, the Registrar has been directed to erase his name from the *Medical Register*."

The Council proceeded to the consideration of the case of George Bell Todd, registered as of 40 Lansdowne Crescent, Glasgow, M.B., M.S. 1884, Univ. Glasg., who had been summoned to appear before the Council on the following charge :—

"That, being a registered medical practitioner, you were on June 3rd, 1912, convicted in the High Court of Justiciary on four charges of procuring abortion (to which charges you pleaded guilty) and were sentenced to seven years' penal servitude."

Mr. Todd was not represented by counsel or solicitor.

The Registrar having read the notice in the absence of a complainant, the Council's solicitor laid the facts before the Council. He read the certificate of conviction and the Judge's observations in passing sentence, and a letter of acknowledgment of the receipt of his notice by Mr. Todd.

Strangers having been readmitted, after the Council had deliberated *in camera*, the PRESIDENT announced the judgment of the Council as follows :—

"I have to announce that George Bell Todd, having been proved to have been convicted of the felony alleged against him in the Notice of Inquiry, the Registrar has been directed to erase from the *Medical Register* the name of George Bell Todd."

The Council proceeded to the consideration of the case of Charles Ernest Turner, registered as of 186 Camberwell Road, S.E., M.R.C.S., L.R.C.P., 1898, who had been summoned to appear before the Council on the following charge :—

"That, being a registered medical practitioner, you were on October 16th, 1912, convicted at the Central Criminal Court of feloniously using an instrument with intent to procure miscarriage and were sentenced to six months' imprisonment with hard labour."

Mr. Turner did not attend in answer to his notice, but was represented by Mr. Jenner, managing clerk of Messrs. Wansey, Stammers and Co., solicitors.

The Registrar having read the notice in the absence of a complainant, the Council's solicitor laid the facts before the Council. He read the certificate of conviction and extracts from the shorthand notes of the Reporter of the Court.

Mr. Jenner applied for an adjournment of the hearing till the following day, as his principal, Mr. Stammers, was unable to be present that day owing to a previous engagement.

Mr. Jenner, on question from the Chair, stated that he had no objection to the presence of Mr. Bodkin as Legal Assessor, although he was aware that Mr. Bodkin had taken part in the prosecution at the trial in the High Court.

The Legal Assessor questioned Mr. Jenner as to the nature of the evidence which his principal desired to bring forward.

Strangers having been readmitted, after the Council had deliberated *in camera*, the PRESIDENT announced that the hearing of this case would be resumed tomorrow at 2 o'clock p.m.

Moved by Sir JOHN MOORE, seconded by Dr. NORMAN MOORE, and agreed to :—

"That the Report by the Public Health Committee in reference to the D.P.H. be received and entered in the Minutes."

Moved by Sir CHARLES BALL, seconded by Sir THOMAS FRASER, and agreed to :—

"That the Report by the Examination Committee on the Returns as to examinations for the Services be received and entered in the Minutes."

The Council received the following nominations from the Scottish Branch Council of a member in the place of Sir David McVail :—Examination Committee : Dr. Norman Walker. Public Health Committee : Dr. McVail. National Insurance Act Committee : Dr. Cash.

Moved by Sir THOMAS FRASER, seconded by Dr. MACKAY, and agreed to :—

"That the nominations of the Scottish Branch Council be adopted."

The Council then adjourned.

THIRD DAY.—THURSDAY, NOVEMBER 28TH.

The President, SIR DONALD MACALISTER, in the Chair.

The Council considered the case, adjourned from Wednesday, November 27th, of Charles Ernest Turner, registered as of 186 Camberwell Road, S.E., M.R.C.S., L.R.C.P., 1898, who had been summoned to appear before the Council on the following charge :—"That being a registered medical practitioner you were on October 16, 1912, convicted at the Central Criminal Court of feloniously using an instrument with intent

to procure miscarriage, and were sentenced to six months' imprisonment with hard labour."

Mr. Turner did not attend, but was represented by Mr. Stammers, his solicitor, who addressed the Council suggesting further adjournment. After Mr. Harper had replied, the Council deliberated *in camera*, and on strangers being re-admitted the PRESIDENT announced that the Registrar had received orders to erase the name of Charles Ernest Turner from the *Medical Register*.

The Council then considered the case of Richard Henry Barber, registered as of 69 Victoria Road, New Brighton, Cheshire, Scottish Triple qualification, 1888. The person practising at that address had received the following notice of an inquiry to be held at which he had been invited to attend:—

"1 New Court, Lincoln's Inn, W.C.,

"November 15th, 1912.

"Sir,—On behalf of the General Medical Council I have to give you notice that on Thursday, the 28th November, 1912, at 2 p.m., the Council will hold an inquiry at 299 Oxford Street, London, W., for the purpose of ascertaining whether the person registered in the *Medical Register* with the name and particulars as follows:—

Name.	Address.	Date of Registration.	Description and Date of Qualification.
RICHARD HENRY BARBER	69, Victoria Rd., New Brighton, Cheshire.	1888, Nov. 1 E.	Lic. R. Coll. Phys. Edin. 1888; Lic. R. Coll. Surg. Edin. 1888; Lic. Fac. Phys. Surg. Glasg. 1888.

is deceased, and whether the said entry has been incorrectly made or fraudulently caused to be made in the said *Register* and should be erased therefrom.

"This notice is sent to you as the person now or lately carrying on practice as a legally qualified medical practitioner in the name of Richard Henry Barber at 69 Victoria Road, New Brighton, aforesaid.

"I am instructed to add that you may attend the inquiry personally, or may be represented by a solicitor with or without counsel. Any communication or application which you may desire to make relating to the matter of inquiry should be addressed to the Registrar of the Council at 299, Oxford Street, London, W., without delay.

Yours obediently,

"CHARLES J. S. HARPER,

"Solicitor to the General Medical Council.

"Richard Henry Barber,

"69 Victoria Road,
New Brighton, Cheshire."

The informants were the Medical Defence Union.

No person answered to the name on its being called. Dr. BATEMAN addressed the Council and examined Mrs. Barber, who had been called as a witness. She asserted that the signatures which had come to the Council were not those of her late husband.

After the Council had deliberated *in camera*, the PRESIDENT announced that the name of Richard Henry Barber would be deleted from the *Register*, as Richard Henry Barber was dead.

The PRESIDENT also expressed the thanks of the Council to Dr. Bateman for the trouble he had taken over this case.

The Council next considered the report of the Dental Committee on the case of Alexander Watson, who had been summoned to appear before the Committee on the following charge:—

"That, being a registered dentist, you were, on September 4th, 1912, convicted at the Eastern Police Court, Glasgow, of the following offence—namely, of being guilty of publicly exposing your person, and were sentenced to thirty days' imprisonment."

"It appeared to the Committee that the case was one which, from the trivial nature of the offence, and from the circumstances under which it was committed, does not call for erasure from the *Register*."

Mr. Alexander Watson attended and addressed the Council, which then deliberated *in camera*. On strangers being re-admitted, the PRESIDENT announced that the Registrar had not been directed to erase the name of Alexander Watson.

The Council then considered the report of the Dental Committee on the case of Alfred James Futcher, registered as of 26 Pretoria Road, Southsea, in practice before July 22nd, 1878, who had been summoned to appear before the Committee on the following charge:

"That, being a registered dentist, you were on October 10th, 1912, convicted at the Portsmouth Quarter Sessions of the following misdemeanours—namely:

"(1) On May 5th, 1909, of obtaining from the North Borneo State Cigar Syndicate, Ltd., 100 cigars with intent to defraud.

"(2) On May 26th, 1909, of obtaining from the North Borneo State Cigar Syndicate, Ltd., 200 cigars with intent to defraud.

"(3) On September 6th, 1911, of obtaining from Jacob Winter one buckle ring and one signet ring with intent to defraud, and were sentenced to nine months' imprisonment in the second division."

Mr. Futcher did not appear. After the Council had deliberated *in camera*, the PRESIDENT announced that the name of Alfred James Futcher would be erased from the *Dentists' Register*."

Proposed by Sir C. BALL, seconded by Dr. NORMAN MOORE, and agreed to, that the report of the Examination Committee on the examinations of the Apothecaries' Hall, Dublin, be received and entered on the Minutes.

Proposed by Sir C. BALL, and seconded by Sir J. FRASER, that the recommendation of the Committee be adopted. With the consent of his seconder this was withdrawn, and the proposer obtained leave to delete the last two paragraphs of the report.

Proposed by Dr. ADYE CURRAN, seconded by Dr. LATIMER, "That the Reports from the Apothecaries' Hall of Ireland be discontinued until such time as the Council may direct. An amendment was moved by Dr. MACKAY, seconded by Dr. NORMAN WALKER, "That Dr. Adye Curran's motion be referred to the Examination Committee for consideration and report at the next meeting of the Council." This was carried and agreed to as a substantive motion.

Moved by Dr. NORMAN MOORE, seconded by Dr. NORMAN WALKER, and agreed to: "That the report of the Students' Registration Committee be received, entered in the Minutes and approved."

Moved by Dr. MACKAY, seconded by Sir CHRISTOPHER NIXON, and agreed to: "That the interim report by the Education Committee be received and entered in the Minutes":—

"The Committee report with reference to their proposals for raising the standard of the Preliminary Examination in General Knowledge that they are at present engaged in conferring with Indian and Colonial Examining Bodies, that they now propose to consult the Government and University Bodies of the United Kingdom, and that they intend to report to the Council on the whole subject at the Session of May, 1913."

Moved by Dr. NORMAN MOORE, seconded by Sir JOHN MOORE, and agreed to that the report of the Pharmacopœia Committee be received and entered on the minutes and approved.

The Committee recommended that Dr. Cash, now an additional member, be appointed an ordinary member in the place of Sir David McVail.

Strangers then, by direction from the chair, withdrew in order that the Council might deliberate on an item of business *in camera*.

Moved by Sir CLIFFORD ALLBUTT, seconded by Dr. LANGLEY BROWNE: "That the Insurance Act Committee be instructed to consider in the interests of medical education the means and arrangements under the Act for providing those aids to diagnosis, treatment and research which modern pathology has made available, and be authorised to make representations to the authorities concerned on these and any other matters arising out of the Act which come within the functions of the Council."

After a discussion, in which Sir J. FRASER, Dr. NORMAN MOORE, Sir C. NIXON, Sir H. MORRIS, Dr. SAUNDBY, Dr. LITTLE and Dr. MACDONALD took part, the motion was carried.

Moved by Dr. NORMAN MOORE, seconded by Sir H. MORRIS, and agreed to unanimously: "That the best thanks of the Council be given to the President for his able services in the chair during the present session."

The Council then rose.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Nov. 30th, 1912.

TREATMENT OF TUBERCULOSIS.

THE treatment of consumption is: (1) Symptomatic, relieving the cough, diminishing the fever, the sweats, but deceives the patient and discourages the attendant; (2) hygienic, rest, aeration, alimentation, to which is also added remineralisation; (3) treatment by serum and tuberculin.

Such are the three methods at the disposal of the medical attendant. To which should the preference be given? To the second or hygienic treatment, says Prof. Brunon, for the others should only come in as auxiliaries.

The hygienic treatment might seem to be easy, but such is far from being the case; its application requires great tact on the part of the attendant, patience and ingenuity so as to vary according to each case a treatment apparently uniform for all.

Therapeutic rest means cessation of all work, manual or intellectual, the horizontal position and rest of the organ (respiration, cough, phonation, etc.)

Cessation of work should be immediate and absolute, independent of any sacrifice.

The horizontal position is rather difficult to regulate. In any case where the malady is in evolution with fever, the temperature should be taken with great exactitude—tachycardia, the patient should be ordered to keep his bed, for the temperature will yield only on that condition. The duration of the cure may last for weeks or months, but as long as the fever continues he must not leave his bed.

Two beds should be at his disposal, one for the day, the other for the night. The day bed may be placed near an open window, for 7 or 8 hours, according to the season.

When the fever has disappeared eight or ten days, the air cure on a reclining chair may be commenced. An ordinary armchair should not be used, as the patient should repose at ease at his full length. The cure in the open air is begun at 8 or 9 o'clock according to the season or the desire of the patient, and up to noon. After dinner he may walk about the garden half an hour or so, and then return to the chair until evening, or from 6 to 8 hours repose in the day, and some time afterwards the hammock may replace the reclining chair while short promenades may be allowed. At this period the weighing machine takes more or less the place of the thermometer. The patient ought to increase progressively in weight.

However, the exercise must be controlled by the thermometer; if the temperature rises somewhat after walking, more rest should be imposed. Short excursions on the sea, horse riding or car riding give good results, but skating, cycling or drives in automobiles should not be encouraged. If the patient returned from his walk in a state of moisture, he should be rubbed with eau-de-Cologne and put to bed for two or three days.

Among the possible evil effects of exercise are dyspnoea, tachycardia, arterial hypotension.

Rest of the organ, discipline of the cough, cure of silence.

Respiration, phonation, cough, should be placed under certain rules from the beginning of the treatment. Long conversations, singing are forbidden. The patient must learn to keep his cough under control

and only cough to expectorate. In certain cases (hæmoptysis) a cure of absolute silence is obligatory. The same may be said of tuberculosis of the larynx, where silence does more effectual good than any local treatment.

The efficacy of rest is frequently very rapid. The moral and physical condition of the patient is improved, appetite returns, dyspnoea relieved as well as the cough, and sleep is possible.

The physical signs are reduced to the minimum. However, it sometimes happens that all these advantages are only transitory.

One must be very prudent and be armed with great patience.

IODIDE OF POTASSIUM IN SYPHILIS.

Iodide of potassium, says Prof. Gaucher, is an excellent adjuvant of mercury but should not be employed indiscriminately. Associated with mercury the iodide increases its action and consequently is prescribed in all the periods of the malady and more especially in the tertiary period where it acts like a charm on gummata.

The counter-indications are first intolerance. From some reason as yet unknown, many persons are unable to take iodide of potassium, which produces on them a disagreeable sensation of congestion in the head, headache, coryza, etc. Hence the necessity of testing the susceptibility of the patient by commencing with small doses.

In lesions of the larynx the iodide should never be given on account of its congesting properties, which might be followed by hæmorrhage.

In a patient suffering from pulmonary consumption as well as syphilis, iodide of potassium should not be prescribed for the same reasons. It is also excluded in acute nephritis with dark and scanty urine, but in amyloid degeneration of the kidney where the urine is abundant and clear, iodide of potassium may be given with benefit.

To conclude: abstinence in lesions of the larynx and great prudence in pulmonary and renal affections.

GERMANY.

Berlin, Nov. 30th, 1912.

At the Gesellschaft für Sociale Medizin, Hygiene und Medizinal Statistik Hr. Prinzing read a paper on the

GREAT EPIDEMIC OF TYPHUS FEVER

in connection with the Russian Campaign, 1813. He said that since the Thirty Years' War there had never been such a great epidemic of typhus of which so little had been known, and especially as regarded the number of victims. It was a double epidemic, the first, associated with the retreat of the French from Russia, and chiefly fell on Prussia and died out in May, 1813. The second followed the campaigns in Saxony and Silesia, and spread over West and South Germany, Switzerland, Austria and France.

Already in Moscow 1,000 cases of typhus had to be left behind, and in the retreat many soldiers fell victims. In Wilna, where the Russians took 30,000 prisoners in the beginning of December, the hospital was crammed full; without fire and without food the sick and dead lay together on foul straw. Of 25,000 inmates of the hospital only 2,500 were left alive by the end of January. Of the Jewish population in and around Wilna, 55,000 died, the Russian army had 62,000 dead, the Eastern Provinces and Russian Poland were overrun with the disease.

In the West the disease began in the summer of 1813, brought in by troops from Austria. After the Passage of the Nieman the dregs of the army scattered in all directions, spreading the disease wherever they went, especially at depots along the military roads, for example, Gumbinnen, Königsberg and Danzig. The latter town had 4,000 deaths from the disease during the siege from January to July in a garrison of 36,000 men and a civil population of 4,000. Berlin was attacked in May, 1813. In the Charité, Horn and Hufeland succeeded in preventing the spread of the disease to the healthy by strict isolation and fumiga-

tion of the patients' belongings. From Berlin the whole provinces of Brandenburg and Saxony were infected, where chiefly Torgau had 6,000 cases of the disease, with 434 deaths. Bavaria, where the danger was recognised in time, and the returning suspected troops were isolated in hospitals, was but slightly affected, and the same in Württemberg, where in 18 communities 165 persons took the disease, with 20 deaths.

During the campaign in Saxony and Silesia the disease which had died out was lighted up afresh, about the middle of May, caused by bodies of Russian and French troops. After the Battle of Katzbach, in Upper Silesia, 9,000 persons died. Then followed Dresden and Leipzig, where 30,000 wounded were left after the battle uncared for in the streets. A total of 80,000 French perished from the pestilence. In Mainz the grave-diggers refused their services, and the frozen bodies lay in heaps before the doors until the setting in of mild weather compelled them to commit the dead to the flames.

In Hamburg a great epidemic began during the siege at the end of 1813; the fugitives and the inhabitants, driven out by Davoust, spread the infection into the neighbouring cities. Between November, 1813, and June, 1814, Bavaria had 18,000 cases of typhus, with 3,024 deaths. It was the same in Württemberg, where half of the medical attendants contracted the disease. In Prussia 200,000 died from the disease, corresponding to a morbidity of about 2,000,000, *i.e.* a tenth of the population of Prussia.

Incomplete hospital accommodation and attendance contributed to the extension of the disease. Citizens called in to assist soon returned home carrying the infection with them. From want of room in the hospitals, convalescents were sent out too soon. Hildebrandt looked upon the disease as one by itself, others thought it was brought about by fatigues of marching and want of food, that it was infectious later, but that it constantly broke out afresh. A Saxon physician thought isolation was injurious, that the disease was rendered more violent by it. Although Hufeland was aware that Cüstrin, although besieged, escaped the disease, he was never quite certain that it spread from person to person. In the French lazarettes there was want of cleanliness. The treatment consisted in fresh air and douching; bleeding did harm. Patients who had to lie in the open air did better than those treated in hospital.

Could such an epidemic be avoided in any future great war? German military sanitation was on the highest footing, but if that of an enemy was not equally without reproach such an epidemic could not be avoided. In 1869 small-pox raged in France, especially where the war was carried. Whilst our well vaccinated troops only suffered slightly, 200,000 French died of small-pox in France. Through the transport of prisoners the disease was carried into Germany, where the epidemic of 1871 and 1872 carried off 17,000 persons, four times as many as fell victims in battle. War authorities as well as the civil population, then, were equally interested in protecting troops from epidemics. It was the duty of the State to assist communities financially in making preparations. Great caution must be exercised in the transport of prisoners, and in the return of troops from the front if they had been engaged in an infected territory. Japan had protected itself from the cholera by causing the troops returning from the Russo-Japanese war to undergo quarantine on three islands. The modern fight against epidemics was of recent origin; it was bound up with the name of Robert Koch.

AUSTRIA.

Vienna, Nov. 30th, 1912.

MEDIASTINOTOMY.

SCHLEMNER, at the Gesellschaft, presented a patient who had been taken into hospital suffering from a deep phlegmonous mediastinitis, being acute, with a large amount of purulent matter, was freely opened on the right side. The history of the case is a long one, as from childhood she had suffered from tubercular

disease in the lumbar portion of the spine, from which she gradually recovered. In the early part of spring and summer of this year she suffered from furunculosis. One of these occurring under the right eye produced lymphangitis and lymphadenitis, which, under conservative treatment with antiphlogistic measures, receded within 14 days. A little later, however, another furuncle appeared on the neck about three finger breadths below the mastoid process dexter. Forming an abscess, a slight incision was made merely to relieve the tension, but not sufficient to clear the whole out. A few days later a large swelling formed, with purulent matter oozing from the mastoid process. From this it was suspected that the abscess had gone deep down into the mediastinum, which was freely opened and drained and the patient kept with her head lower than the body.

HERPES ZOSTER.

Zumbusch brought forward a man, *æt.* 74, with an aberrant form of vesicle resembling herpes zoster. The whole skin from the hair of the head to the feet was covered with these vesicles.

Hermann said he had seen several cases of this sort of vesicle on the second or fourth day after an attack of herpes zoster, and to him they appeared a varicelle universal exanthema of the skin. He found it general over the mucous membrane, and even epidemic sometimes, which corresponded to a general infection, which may be considered a virus in the blood exhausting itself in the skin.

RUPTURE OF THE SPLEEN.

Khautz exhibited a lad, *æt.* 12, who had been received into hospital with rupture of the spleen, which had been extirpated shortly after reception. On laparotomy being performed, upwards of a litre of dark fluid blood was found in the hypochondrium, and in the upper part of the spleen, near the hilus, a wide tear in the organ, the result of the accident. The patient made a good recovery. He showed a preparation of a spleen from another patient who had been operated on after an accident in a motor car. This case was more complicated, as the patient had fracture of the right side of the skull and was unconscious, but the fever assisted the diagnosis with the blood found in the abdomen, but the pain in the left shoulder, which was severe in the first case, was masked by the unconscious condition of the second.

UNITED STATES OF AMERICA.

New York, Nov. 21st, 1912.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA.

(Concluded from our last issue.)

CRILE'S METHOD OF ANÆSTHESIA.

At the meeting in the Waldorf-Astoria Hotel on the evening of November 12th, Dr. George W. Crile, of Cleveland, Ohio, read a paper on the method of anæsthesia and anoci-association. This method has been described already in the MEDICAL PRESS AND CIRCULAR, and it only remains to be said that Dr. Crile again asserted that the mortality rates had been greatly reduced in his clinics in Cleveland by the employment of this form of combination anæsthesia. He added that nitrous oxide was superior to ether as a general anæsthetic, because it protected the blood cells by diminution of oxidation. In addition to this, the exclusion of harmful stimuli enabled the patient to become safely and agreeably unconscious for the proposed operation.

Dr. Otrid Foerster, of Breslau, Germany, discussed indications and results of

EXCISION OF THE POSTERIOR SPINAL ROOTS

in man. This paper was for the most part an enumeration of the number of operations of this kind he had performed for the relief of various diseases and affections.

Dr. Charles H. Frazier, of Philadelphia, dealt with some problems and procedures in the surgery of the spinal canal.

Dr. D'Orsay Hecht, of Chicago, read a paper on

the "Surgery of the Spinal Cord" from the neurological standpoint, and in the course of his remarks said that with regard to serous meningitis he took issue with the text-book view that treatment should be largely surgical. Their diagnoses were not clinically refined, and they could not advance far until more of the psychical side was put before them.

Perhaps, on the whole, the most interesting event of the meeting, that is so far as reading of papers and discussion were concerned, was the symposium on

INTESTINAL STASIS

which was held in the ballroom of the Hotel Waldorf-Astoria on the evening of November 14th. Dr. R. R. Smith, of Grand Rapids, Michigan, the first speaker, discussed enteroptosis in women, and then

Mr. Arbuthnot Lane, of London, in a long and able paper, gave his views on chronic intestinal stasis and its treatment. He recognised the fact that much of the ill-health of enteroptic women, and indeed of a very large number of sufferers, was due to auto-intoxication, a result of delay of the stomach and large and small intestines in emptying themselves, especially the small intestine. Furthermore, owing to the poisoning of the entire system by poisons generated by intestinal stasis, and which enter the blood stream, a large variety of ailments and diseases may be attributed to this cause. Even such remote diseases as cancer and tri-facial neuralgia. Mr. Lane stated that he had obtained excellent results by short-circuiting the bowels in such a manner as to remove the obstruction and to cut out a large amount of the absorbing surface, thus preventing auto-intoxication to a large extent. Mr. Lane described the way in which obstruction might be gauged by means of bismuth and the X-rays, and demonstrated this by illustrations on the screen.

Dr. John F. Clark, of Philadelphia, took a far more conservative view with respect to operative procedures for the relief of intestinal stasis. He drew attention to the severity of such operations, and said that he was of the opinion that these cases should be selected with the greatest care, and operations performed only when every other means had failed to relieve an otherwise thoroughly deplorable state of health.

Dr. Robert C. Coffey, of Portland, Oregon, read a paper entitled "replacing and retaining operations in the treatment of gastric and intestinal stasis," in which he reviewed the operations performed and suggested for these conditions. He also gave the results of operations done by himself which, while less serious than some of those which had been proposed, have met with almost no primary mortality, and have resulted in marked benefit to the patient.

Dr. Joel E. Goldthwait, of Boston, Massachusetts, who is an orthopaedic surgeon, stated that he held the view that deformities such as round shoulders, changes in spinal configuration and flat, collapsed chest conditions, which invariably accompany visceral prolapse, were largely causative in producing it. Thus the treatment of the intestinal stasis by medical or surgical means was incomplete unless the strain were removed.

THE CANCER PROBLEM.

Of course, this perennial subject was discussed at the meeting. A large number of the visiting surgeons went to the laboratories of the Rockefeller Institute for Medical Research when Dr. Peyton Rous explained his methods for studying cancer. Dr. Rous made this statement:—"I believe that a cure for cancer will be discovered before the cause of the disease is known, but whether this will be in our lifetime, naturally I am unable to say." Moreover, the Clinical Congress decided that the time had come for the medical profession to conduct a campaign of publicity throughout the country in order to let everyone know the importance of early operation in the disease. The Congress accordingly passed the following resolutions:—

"Be it resolved, That the time has arrived when, if the surgeons of America are to do their duty to the citizens of this country, a campaign of publicity should be at once undertaken to bring to the attention of every woman in this country the early symptoms of cancer of the womb, and to point out that if the disease be

detected in the early stages it can often be cured. Be it further resolved, That this society at once appoint a committee of five, to be named by the President of the Congress, to disseminate this information. And further, That this committee be instructed to write, or have written, articles to be published in the daily Press, the weekly or monthly magazines, as may prove most expedient. And, further, that they report their progress for the year to the next annual meeting. Dr. Edward Martin, of Philadelphia, President of the Congress, appointed the following surgeons as a committee to carry out the purposes of the resolutions. Dr. Thomas S. Cullen, of Baltimore, Chairman, Dr. Thomas Howard C. Taylor, of New York City, Dr. C. Jeff Miller, of New Orleans, Dr. F. F. Simpson, of Pittsburg, and Dr. E. C. Dudley, of Chicago.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

CRITICAL FINANCIAL POSITION OF THE WESTERN INFIRMARY.

SIR MATTHEW ARTHUR presided at the 38th annual meeting of contributors to the Western Infirmary, and moved the adoption of the report, remarking that so far as treatment of patients was concerned they had accomplished a satisfactory year's work. The number of outdoor patients was 9,142, showing an increase of 146 over the previous year. Unfortunately there was a slight decrease in their ordinary revenue—not due to a falling off in contributions; the subscriptions from employees were quite 8 per cent. more than last year. The net result was that after expending the ordinary and extraordinary income their capital had been reduced by £6,989 in order to meet the deficit in the years' workings. He thought they all realised that the financial position of the Infirmary was far from satisfactory. The unrestricted capital of £6,612 was but a slender reserve when their annual ordinary expenditure exceeded £40,000. The financial support they received had not grown with the growth of the Infirmary, probably because the public did not altogether realise that growth. There were always patients waiting admission, so their admissions were not in excess of the needs of the community. They could not expect any reduction in the cost of the beds, and the only way to economise was to reduce the number of patients. It would be most unfortunate if the usefulness of the Infirmary were to be in any way impaired by the lack of funds, and they very earnestly appealed for increased support.

GLASGOW PROPOSALS AS TO THE LISTER MEMORIAL.

A meeting of the Executive Committee was held in the City Chambers, under the presidency of the Lord Provost, and amongst others present were Sir Hector Cameron, Mr. A. E. Maylard, and Mr. J. D. Hedderwick. The principal business was to receive a deputation from the Royal College of Surgeons of Edinburgh, which deputation comprised the President of the College (Professor Caird), the ex-President (Mr. George A. Berry), and Mr. Stiles; and to discuss the practicability of co-operation between the two cities in establishing a Scottish national memorial to Lord Lister. It was suggested that the memorial might take the form of laboratories for research, but after a lengthened interchange of views it was felt that to promote such a movement would appear to be disloyal to the London Committee, which had already recommended the establishment of an international Lister Memorial Fund for the advancement of surgery, from which either grants in aid of researches bearing on surgery or awards in recognition of distinguished contributions to surgical science should be made irrespective of nationality. It was resolved to recommend that the Lord Provosts of Edinburgh and Glasgow and the Principals of the Universities of these two cities, who are also members of the London Executive Committee, should be requested to keep prominently

before that committee the claims of Scotland for an adequate share of the grants, and that these gentlemen should be entrusted with the administration of any funds in Scotland that may be granted from the memorial. The Edinburgh deputation having retired, the Committee took into consideration the question of the character of the Glasgow memorial. It was resolved to recommend that subscriptions be invited (a) towards the erection in Glasgow of a monument to Lord Lister and to the provision of an endowment for the equipment and maintenance of the proposed Lister Museum in the Royal Infirmary, accommodation for which will be provided in one of the wards in which Lord Lister first put into practice his system of antiseptic surgery, and which ward the managers of the Infirmary have agreed to retain for the purpose; (b) towards the Lister International Memorial Fund promoted by the London Committee. Subscribers will be requested to intimate what proportions of their contributions are to be assigned to the local and to the international funds respectively, but when no such intimation is given the Executive Committee may apportion contributions to either or both funds at its discretion.

MUNICIPAL DUTY IN REGARD TO BURIAL REFORM.

Dr. Ebenezer Duncan presided at the annual meeting of the Scottish Burial Reform and Cremation Society, Ltd., in the Merchants' House, Glasgow, and moved the adoption of the report. The Society had been in operation over twenty-five years, and now their work divided itself into two branches. In the first place they endeavoured to bring about a reform in the present method of burial, which was not only insanitary, but also unnecessarily expensive, but he had to admit that they had not been able to make any very great change in the habits of the people. The common ground, at least, was overcrowded by the method of pit burial, and this method was objectionable, not only from the point of view of sentiment, but also from the sanitary standpoint. The other branch of the Society's work had been to foster the practice of cremation, which he believed to be the only alternative to a continuance of this system of pit burial in common ground. From this point of view the advance of cremation was to be welcomed, and they were glad to find as a matter of fact all over the civilised world cremation was advancing with rapid strides. It was necessary to force upon the large corporations, such as Glasgow and Edinburgh, that there must be some change in the method of pit burial, because there was no doubt it was a very great source of injury to the public health in the large cities to have these great, crowded cemeteries surrounded by dwelling houses, and the ground, the air, and the water all round about polluted by such masses of decomposing material as they had in these places.

Professor Glaister, in seconding the motion, noted that St. Columba's, the leading Presbyterian Church in London, was open for the reception of urns, and that in Westminster Abbey and St. Paul's Cathedral the ashes of famous men had been placed therein. He was not, however, sure that the religious prejudice in Scotland would be quickly overcome. Steady progress was being made in the education of the people by the persistent work of the Society, and he was of the impression that they were at the turning point. In Glasgow they had annually to dispose of between fifteen and sixteen thousand bodies, and according to the present methods of interment that meant a large amount of ground practically set apart for all time, which was a condition which could not go on indefinitely.

ABERDEEN ROYAL INFIRMARY EXTENSION.

The Aberdeen Royal Infirmary new out-patients' department was formally opened on Monday afternoon, November 25th. The new premises consist principally of an operating theatre, dispensary, and casualty ward, and are situated on the opposite side of Woolmanhill from the existing main block. The casualty ward has thus been entirely removed from the old portion of the Infirmary, and all out-patients are to be treated in the new building.

GARTLOCH DISTRICT ASYLUM.

In the 15th annual report of this Asylum Dr. Parker states that 258 patients were admitted during the year, a distinct falling off as compared with the previous year, when the maximum number of 307 was attained. From the point of view of recovery, the character of the cases admitted is very poor—only 76 first attacks of less than a year's duration, and 182 over a year's duration, congenital imbeciles, or not first attacks. Of the admissions 28 were congenital defect or epilepsy, 17 general paralysis, 43 dementia paranoïa, or chronic delusional insanity. The cases in the Asylum are becoming more and more purely residual, hence the wards are more troublesome than they used to be on account of the large number of noisy, irritating patients. The want most urgently felt is a male-staffed bed ward for tuberculous cases. The present sanatorium for tuberculous cases is not suitable for a male staff on the male side, but is quite suitable for bed-ridden and semi-bed-ridden senile cases, feeble epileptics, and advanced general paralysis. The recovery rate is 33 per cent. This low rate is due to the treatment of incipient and transient forms of insanity in the mental wards of Duke Street Hospital. Boarding suitable unrecovered patients is practised, but leaves a larger proportion than usual of noisy, troublesome patients in the wards. The relative cost of treating these is raised, on account of the larger staff needed. Since the opening of the Hospital in 1898 the percentage mortality from tuberculosis has been about 1.5, and from general paralysis about 2.7. Among the chief causes of insanity in the patients admitted Dr. Parker notes syphilis and alcohol. Syphilis was present in 40 cases, and alcohol was the main determining factor in 54. Of the cases admitted in whom a reliable history was obtained as to the habits of the parents 59.4 had a history of parental abuse of alcohol, while in those patients below 26 years at the first attack of mental disease the percentage of parental alcoholism was 84. With the Wassermann test 21 per cent. of a consecutive series of 75 females, and 35.8 per cent. of 54 consecutive male patients gave positive reactions. The blood serum of 94 general paralytics gave a positive reaction in all save one instance, and in this one the cerebrospinal fluid gave the reaction. The sera of 329 cases of insanity, other than general paralysis, gave 16.4 per cent. of positive reactions. Such figures show how widely spread and damaging syphilis is, and go far to explain the prevalence of general paralysis. The report contains the usual statistical tables, and the Commissioners of Lunacy speak in favourable terms of the management of the institution.

BELFAST.

THE INSURANCE ACT.

THE question of the payment of members of hospital staffs for attendance on insured patients has excited a good deal of interest in Belfast medical circles. The staffs of the three hospitals which are most interested in the matter, the Royal Victoria, the Mater Infirmorum, and the Forster Green Sanatorium, met to discuss it, and decided that for the present at any rate they would accept no fees, but would continue to act as honorary members of their respective staffs. The Local Medical Committee, however, have reversed this finding, and decided that a charge of at least five shillings per week for ordinary treatment of insured persons should be made:—that is, of course, for persons sent to hospital as insured patients. The two general hospitals have not yet formulated any plan for the treatment of such persons, and many members of the staffs think that such patients should not be accepted. But with the Forster Green Sanatorium the question was an urgent one, as many county authorities were inquiring as to the terms on which patients sent by them could be accepted, and no answer could be given by the Board till the staff decided on their terms. They have now done so, and their terms have been accepted by the Board, and notice is being sent to the various bodies interested. The charge for maintenance

in the Sanatorium is 25s. per week, over and above all charges for treatment. The medical charges are fixed as follows till April 15, 1913, after which they are subject to revision:—for ordinary treatment, 5s. per week; for consultation, £1 1s.; for operation, £5 5s.; for consultation with the dental surgeon and extraction if necessary, £1 1s. By ordinary treatment is meant such treatment as patients at present receive, generally two visits a week from a member of the honorary staff. Consultations include visits from the surgeon and laryngeal surgeon, who are members of the staff. For a short formal certificate a charge of 5s. will be made, and for a full report upon a case, 10s. 6d.

Medical men will watch with interest to see how far these terms are accepted by the local authorities. No doubt some of them will think them too high, as their minds have been prejudiced by the report that patients will be treated at certain Irish sanatoriums, at an inclusive charge of one guinea per week. In Belfast the house charge of 25s. per week hardly pays out-of-pocket expenses, and leaves nothing for depreciation of buildings, etc., or for medical treatment. It has been suggested that in a large sanatorium a saving would be effected by dismissing the honorary staff and appointing a whole-time medical officer, but a little examination shows that the saving might not be very much after all. An experienced man, fit to take entire control of such an institution, would be worth at least £500 per year, and this would be equal to a payment of 5s. per week by 38 patients, or say 40 beds, allowing for vacancies. If there were more beds, an assistant would be needed. Further, this allows nothing for consultations with specialists, which would certainly be necessary at times, and would have to be paid for at a higher rate if the specialist was not a member of the staff. If an inclusive fee is fixed which will cover all these contingencies, it is not likely to be much lower in the end than the terms now proposed by the Forster Green Sanatorium.

EUGENICS.

A meeting of the Belfast Branch of the Eugenics Education Society was held in the Medical Institute on November 28th, the Bishop of Down presiding. Dr. W. A. Potts, lecturer on Pharmacology in the University of Birmingham, and late medical investigator to the Royal Commission on the Care and Control of the Feeble-minded, delivered a most interesting lecture on "The Feeble-minded." Dr. Potts urged that while drink, ill-health, bad feeding, and insanitary homes might all be contributing causes, the main cause of feeble-mindedness was a mentally defective ancestry, and the only cure was to have the feeble-minded removed from the ordinary world to a place of safety. They should never go to prison or to ordinary charitable homes, but should be placed in custodial homes or farm colonies, where they should be kept, not for an arbitrary period, but till they were able to take care of themselves. He suggested that all should join in bringing pressure to bear upon the Government to take up again the Mental Deficiency Bill. A resolution on the lines of this suggestion was moved by Bishop D'Arcy, seconded by Dr. Calwell, and passed. Professor Lindsay and Professor Gregg Wilson also spoke.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THERAPEUTIC IMMUNISATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR, In his inaugural address to the students of the Meath Hospital, published in last week's MEDICAL PRESS AND CIRCULAR, Dr. Boxwell said: It is sufficient here to remind you that Pasteur may be said to have discovered microbes, and that was less than sixty years ago."

You were so good as to publish a letter I addressed to you on "The late Dr. Smart," in which I confessed my ignorance of the very important discovery he made

in the year 1865 of the germs which were the origin of Rinderpest. Dr. Boxwell is not correct in stating that "Pasteur may be said to have discovered microbes." I have before me the "Reports on Rinderpest to the Right Hon. the Lord Provost, Magistrates, and Town Council of the City of Edinburgh," and the lectures delivered by Dr. Smart on "Germs, Dust and Disease." On page 6 of the reports there is a short statement in tabular form, "Description of Germs and Dates of their Discovery."

1. Rinderpest Germ discovered and published on 12 Sept., 1865 (Smart), etc., etc.

And below this is the following: "Pasteur's researches on silkworm diseases began in 1867, but the results of these remarkable investigations were not published until 1870."

In Dr. Smart's Lectures, p. 7, the following is stated: "I found rod-like germs abundantly present in the blood of animals attacked with cattle plague, one of the most intensely infectious diseases that ever visited this country." . . . "So far as I am aware it was the first time that they were shown to exist in the blood of living animals."

If Dr. Boxwell has never read the two works referred to he will feel an interest in doing this, for he must be anxious to be accurate when he is lecturing to his students at the Meath Hospital.

I am, Sir, yours truly,

ROBERT LEE.

West Drayton, Nov. 30th, 1912.

THE ANTISEPTIC TREATMENT OF PHTHISIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been drawn to the valuable correspondence in your paper relating to the Antiseptic Treatment of Phthisis. I wish first of all to state that I am not a medical man, nor do I profess to have any medical knowledge, although as a son of the late Dr. Robert Lee, F.R.S., and having two brothers who are physicians, I have taken an intelligent interest in medical matters from an engineer's point of view, in endeavouring to help the profession in the design and construction of apparatus that I felt might be of interest in the treatment of disease.

It was in this connection that, at the suggestion of my brother, Dr. Robert Lee, I endeavoured to perfect a simple apparatus which would provide a method for the production and inhalation of antiseptic vapour in such form that the medical attendant could absolutely determine, as required, the definite percentage of antiseptic to be administered to the patient. There were many difficulties to overcome, but I have now constructed an apparatus which enables the physician to have at his command a method of producing a continuous supply of air, of suitable temperature, impregnated with a definite proportion of antiseptic, and with such force that it can be inhaled by the patient (whether recumbent or otherwise), or propelled into a room.

The apparatus is perfectly simple and requires very little attention to operate. It consists of a boiler to which is fitted (1) a safety valve, (2) a brass dome, having a small orifice in the centre, and (3) a mixing chamber provided with air-inlets, fitted directly over the dome. Fitted to the mixing chamber is a jointed exit tube, which may be set in any position both horizontally or vertically, to convey the medicated air in any required direction. A good adjustable spirit stove or bunsen gas burner is required.

The boiler having been charged with a quantity of water and medicated solution as may be prescribed, and the mixture boiled, a jet of medicated steam is forced under pressure (regulated by the safety valve) into the mixing chamber, where by injective force, this jet of steam draws in a powerful current of air through the air-inlets, simultaneously warming and medicating the air and driving it through the tubes, whence it issues at a temperature suitable for immediate inhalation. The velocity of this current can be raised from 250 to 300 feet per minute, according to requirements.

It of course only needs stating that the principle of the apparatus could be used for supplying entire build-

ings or sanatoria with air impregnated with antiseptic in quantity.

But of course the essential point from the medical point of view is that (as my brother ascertained in his prolonged investigations of antiseptic vapours) when a mixture of phenol and water is boiled the steam will contain the vapour of phenol in exactly the same percentage as the water with which the phenol is mixed.

All I claim for the apparatus is that it provides an efficient means of producing and distributing phenolised or medicated air with continuity and force for all purposes where antiseptic vapours may be of benefit.

I am, Sir, yours truly,

SYDNEY LEE.

4, Albany Terrace, London, W.
28th November, 1912.

THE HOME RULE BILL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—What are our Irish Medical Bodies doing? Do they really propose to make no effort to secure compulsory pensions for the Irish Poor Law Medical Service? Many, no doubt, don't think the Bill will pass, but if it does pass they will be called to a stern account. How comes it that everybody else is protecting himself?

I am, Sir, yours truly,

Cashel, WM. THOMAS LAFFAN.
November 25th, 1912.

THE RECENT LAW CASE AND INCOME TAX.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Many taxpayers who have received the usual blue notices of charge for the current year are, it appears, under the impression that in view of the recent decision in the action *Gibson Bowles v. the Bank of England*, they need not trouble about appealing within the time stated on the notices, reasoning that the income tax laws are in abeyance for the current year, and will remain so until a Finance Act for 1912 shall have been passed. The only safe course is to give notice of appeal against an excessive assessment at once, as, in our opinion, it is certain that the Inland Revenue authorities will continue to act as though a Finance Act for 1912 had already been passed. Any action against the Inland Revenue commenced now would probably not come on for hearing before such an Act will have been passed, and it is certain that when the Act is passed it will be found to contain provisions legalising the assessments already made for the year ending April 5th, 1913.

I am, Sir, yours truly,

E. MONTAGUE,

Secretary, The Income-tax Adjustment Agency,
London, E.C.

OBITUARY.

DR. ROBERT FLETCHER.

By the recent death of Dr. Robert Fletcher, the medical bibliographer, at the age of 90, a distinguished member of the medical profession has been removed from our midst. A native of Bristol, he received his medical education at the old infirmary in that city and at the London Hospital. He qualified as M.R.C.S.Eng. in 1844, and also became M.D. of the University of Columbia. At the outbreak of the American Civil War he was appointed Surgeon to the 1st Regiment of the Ohio Infantry, and served in the field for two years, retiring with the rank of lieutenant-colonel, and being afterwards promoted to colonel in recognition of his services during the war. Soon afterwards he inaugurated the Army Medical Library at Washington, which has grown to be probably the most important collection of its kind in the world. Dr. Fletcher was associated with Dr. J. S. Billings, the present head of the New York Public Library, in compiling and editing the *Index Catalogue of the Library of the Surgeon-General's Office, Washington, U.S.A.*, and was solely responsible for a number of the volumes. Dr. Fletcher and Dr. Billings were also associated in

the compilation of the *Index Medicus*, a monthly journal giving the current medical literature in all languages. After a lapse of several years, this work was revived by the Carnegie Institution of Washington; Dr. Fletcher was chosen editor, and its extraordinary accuracy is mainly due to him. It has been stated that to the last volume every page of the *Index Catalogue* was read by him in proof. Since 1880, 32 folio volumes have been issued, usually of about 1,000 pages each, including about 10,000 author titles, and representing from 4,000 to 5,000 bound volumes and from 7,000 to 10,000 pamphlets. The second series, now finishing with the letter S, forms the catalogue of a library which last year contained 176,600 bound volumes and 315,414 pamphlets. Dr. Fletcher wrote several papers on anthropology, folk-lore, and on the older English poets and dramatists. He formerly lectured on medical jurisprudence at one of the Washington schools, and afterwards gave an annual course of lectures on the subject at the Johns Hopkins Hospital School at Baltimore. A few years ago he had a serious illness and made a slow recovery, but he generally enjoyed an old age of great mental vigour and was at work almost to the last. In 1910 the Council of the Royal College of Surgeons of England conferred upon Dr. Fletcher the honorary medal of the College for "distinguished labours eminently conducive to the improvement of natural knowledge and the healing art." The medal is rarely conferred, and it may be mentioned that a previous recipient was the late Lord Lister. The presentation of the medal to Dr. Fletcher was made at Washington on behalf of the English College by Mr. Bryce.

MR. G. W. ARMSTRONG, OF BOURNEMOUTH.

We regret to record the death of Mr. George William Armstrong, M.R.C.S., aged 72, which has taken place at Somerset House, Chine Road, Bournemouth. The deceased, who was well known in naval circles, was the only son of the late Dr. Armstrong, of Queen Anne's Gate, and for a period of nearly 30 years was Resident Medical Officer and Deputy Superintendent at the Royal Hospital Schools at Greenwich, a post with which was associated the medical charge of the officers and residents at the adjoining Royal Naval College. In the absence of his chief, the late Capt. Burney, C.B., through ill-health, it fell to Mr. Armstrong to assume the position of Superintendent for a lengthened period, and the efficiency with which he discharged those duties was recognised by the Admiralty by the grant of a special pension when failing eyesight compelled his withdrawal some twelve years since. Mr. Armstrong's death will be greatly regretted by the large number of naval officers who were brought into contact with him at Greenwich. Amongst these he was a very general favourite by reason of the kindness and geniality of his character, no less than the readiness with which he was always prepared to place at their disposal, at any hour of the day or night, all the resources of his professional skill.

DR. R. H. TRAQUAIR, LL.D., F.R.S., OF COLINTON.

We regret to announce the death of Dr. Traquair, which took place at Colinton on November 22nd. Although a graduate in medicine, Dr. Traquair never practised his profession but devoted himself to pure science, and attained a European reputation in the domain of palæontology. He was born in 1840, and after his graduation became one of Goodsir's demonstrators. At the suggestion of his chief he studied the asymmetry of the flatfishes, and was awarded a gold medal for his work. During the rest of his life the study of fossil fishes engaged the greater part of his energy. In 1866 he became Professor of Natural History at the Royal Agricultural College, Cirencester; in 1867 Professor of Zoology in the Royal College of Science, Dublin; and in 1873 he was appointed keeper of the natural history collection in the Royal Scottish Museum, Edinburgh, a post which he held until his retirement in 1906. By his work and study in Edinburgh, on morphological structure rather than mere outline of the body or configuration

of scales and teeth, ichthyology has been revolutionised, and the classification and nomenclature of Agassiz have been overturned. He published upwards of 130 papers on zoological and palaeontological subjects, chiefly fossil fishes, and has left behind him a manuscript catalogue of the fossil fish in the museum. He received many honours: at an early age he was elected a Fellow of the Royal Society, and was awarded numerous medals and prizes by the Royal Societies of London and Edinburgh. He is survived by his widow, a daughter of Dr. William Moss, physician, Dublin, and by two sons and a daughter.

DR. J. WALLS WHITE, OF GLASGOW AND UDDINGSTON.

THE death occurred on Saturday night, November 23rd, with startling suddenness, of Dr. James Walls White, Brunalb, Belleisle Avenue, Uddingston. Dr. White was 73 years of age, and was a native of Orkney, and had been practising in Uddingston for 30 years. He was attending his usual duties on Saturday, even to his surgery at 8 o'clock, and afterwards had reason to call upon a patient, reaching home about 9 o'clock. Shortly afterwards he complained of pain in his left side, and feeling faint was put to bed, but never recovered.

Dr. White took an active and keen interest in the local affairs of the district, and for a number of years was one of the Uddingston representatives on the Parish Council of Bothwell, and also a member of the Park United Free Church, Uddingston. He was for a long time connected with the old established firm of manufacturing chemists, Messrs. J. and I. White, Paterson Street, Kingston, Glasgow. Dr. White leaves a widow, two sons and four daughters to mourn his loss.

MEDICAL NEWS IN BRIEF.

A Play with a National Health Moral.

An interesting play in support of the crusade against consumption was produced last Wednesday at the Royal Court Theatre conjointly by the Women's Imperial Health Association and the Women's National Health Association of Ireland. The moral of the play is that no one need despair on account of poverty or ill-health, and a battle royal rages between Ignorance, Squalor, Worry-worry, and Purity, Love, Common Sense and Sunshine, the battlefield being a poor Irish cottage. The part of the little Irish girl to whom the good fairies reveal themselves was very cleverly played by Miss Florrie Ryan. The Royal Hospital for Diseases of the Chest, City Road, the City of London Hospital for Diseases of the Chest, Victoria Park, and St. Luke's Hospital for Consumption sent nurses to sell programmes. The theatre was crowded and many interesting people were to be seen, including the Earl and Countess of Aberdeen, who came over from Dublin to see the performance. Others present were Lord and Lady Haddo, Miss Violet Asquith, Lady Duckworth, Lady Critchett, Lady Mackenzie Davidson (who brought a large party), the Hon. Mrs. Dudley Gordon, Viscountess Wolmer, Lady Pirrie, Mrs. Martin Harvey, Mr. Alfred Butt, and Mr. Stuart de la Rue. The prologue was rendered by Miss Irene Vanbrugh, who indicated the keynote of the play—the triumph of knowledge over ignorance and the consequent defeat of the demon of tuberculosis. To many it is not news to hear that sun and air mean life, that temperance, slothful habits and bad food mean disease, but to know is not always to apprehend. We give our hearty support to the present or any other public-spirited effort to bring home the lessons which are of national importance.

Royal Society of Medicine.

A SERIES of four *conversazioni* was held at the Royal Society of Medicine last week. The President, Sir Francis H. Champneys, received the guests. Among those present were Sir Rickman Godlee (President of the Royal College of Surgeons), Sir

Donald MacAlister (President of the General Medical Council), Surgeon-General Sir James Porter, Surgeon-General Sir William L. Gubbins, Sir Arthur M. Branfoot, Sir Henry Morris, Sir St. Clair Thomson, Sir William Whitla, Sir Havelock Charles, Sir William Watson Cheyne, Sir David Ferrier, Sir Shirley Murphy, Sir James Reid, Sir David Semple, Dr. Robert Saundby, Mr. E. Parker Young, Dr. James Little, Dr. William Hunter, and Miss Scharlieb. Of the many exhibits, the most striking, perhaps, was the demonstration by the librarian, Mr. Hewett, on the epidiascope of some of the rare and curious volumes that are in the possession of the Society. Among these was Sir Thomas Browne's "Religio Medici," being a Latin edition of the work published in 1650. A remarkable series of engravings were also thrown upon the screen from Sir Samuel Garth's "The Dispensary," a volume that satirises the opposition of apothecaries to the scheme of establishing out-patients' rooms. Some interesting displays were afforded in the cinematographic films by Messrs. Pathé of various medical and biological subjects, which included pictures of sea life, of the circulation of the blood, of agglutination, of phagocytosis, of the development of sea urchins' eggs, and of the effect of a specific drug on a bacterium. Mr. Deane Butcher, in the Library, gave a demonstration of Professor Leduc's osmotic growths, while in the west lecture hall Messrs. Leitz exhibited various forms of optical apparatus. During each evening a musical programme was given by Mr. Godfrey Holbeck's Orchestra.

Women's National Health Association—Annual Meeting.

THE fifth annual meeting of the Central Dublin Branch of the Women's National Health Association was held last Friday afternoon in the Theatre of the Royal Dublin Society. The Countess of Aberdeen, President of the Association, presided, and recounted the action taken by the Samaritan Committee in regard to the domiciliary treatment of tuberculosis.

Dr. Crowe, medical superintendent of the Collier Dispensary, read his annual report, which stated that 1,176 cases had been dealt with. That worked out at 80 visits per day. The splendid number of 7,555 visits had been paid during the year.

The following resolution was adopted:—

"That the branches of the Women's National Health Association in the City and County of Dublin do request the Lord Mayor of Dublin, and the Chairman of the Dublin County Council to call a meeting to consider the formation of voluntary care committees, representative of all forms of charitable work, to act in conjunction with the official committees under the Dublin County Borough Council, and the Dublin County Council, administering sanatorium benefit and treatment for tuberculosis under the Insurance Act of 1911, and the Tuberculosis Act (Ireland) of 1908."

University College, Dublin.

THE inaugural meeting of the third session of the Medical Society in connection with University College, Dublin, was held last week in the Great Hall of the College, Stephen's Green, Dublin. The President, Dr. Denis J. Coffey, presided. There was a large attendance.

Professor B. Collingwood, M.D., read a paper on "Some recent investigations into the coagulation of blood and their practical application," in which he discussed the result of experiments and researches in various matters of a complex nature relating to blood. Among those who took part in the discussion were Professors Thompson and McWeeney, Sir W. J. Thompson, Drs. Parsons and Farnon.

A Tuberculosis Dispensary for Lambeth.

THE Lambeth Borough Council have adopted a scheme for the establishment of a tuberculosis dispensary at Effra Road, Brixton, and propose to pay the Medical Officer in charge of the institution a salary of £300 a year. The Local Government Board have written to the Council stating that, having regard to the population of the borough and the extent and character of the duties attaching to the post, they doubt whether a salary starting at £300 a year is sufficient to attract medical men possessing the necessary qualifications and experience.

NOTICES TO CORRESPONDENTS, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

SENIOR STUDENT (Dublin). Should endeavour to obtain a house-surgery at a recognised children's hospital; the fact of his having filled such a post will not only give him the practical knowledge he now seeks, but would be a stepping-stone towards the goal of his ambition. One such post offers itself at the present moment at the Hospital for Sick Children in London, which stands at the head of its class. For form of application our correspondent should at once apply to the Secretary, according to the advertisement in another column.

MEDICAL FEES IN BYGONE TIMES.

APROPOS of the fees offered by the Chancellor of the Exchequer to the doctors, it may be stated that at the beginning of the eighteenth century the usual fees to physicians and surgeons in England were "to a graduate in physic, his due is about ten shillings, though he commonly expects or demands twenty. Those that are only licensed physicians, their due is no more than six shillings and eight pence, though they commonly demand ten shillings. A surgeon's fee is twelve pence a mile, be his journey near or far; ten groats to set a bone broke, or out of joint; and for letting blood one shilling; the cutting or amputation of any limb is five pounds; but there is no settled fee for the cure." The system of regulating the fee according to the pocket of the patient is almost as old as history.—*Westminster Gazette*.

DR. BRAND (Driffeld).—We regret the delay in publication of your paper on account of great pressure on our space. Proof will be forwarded to you in the course of the present week.

MR. E. B. (Maidstone).—The report in question will shortly be noticed in our columns.

AN INVOLVED PRESCRIPTION.

A LADY staying at an hotel was frightened by a noise like that of a person running about in a room over the one she occupied. The noise went on at intervals for two nights and then changed as if the occupant had gone mad and was jumping about. After making necessary inquiries, the proprietor ascertained that the author of the mystery was a sick foreigner obeying the imperfectly understood directions of an English medical man: "Take the medicine two nights running, then skip a night."—*Everyone's Story Magazine* for December.

DR. T. A. W. (Beds).—The saley-arsenate of mercury, known as *arsenal*, has been found by Frey to possess a rapid action in syphilitic affections of the nervous system appearing to be even superior to salvarsan. It has also been reported by Subourant to be of service in psoriasis when injected subcutaneously. The preparation is said not to give rise to general or local symptoms of poisoning.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, DECEMBER 4TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OPHTHALMOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Discussion opened by Dr. Leonard Hill, F.R.S. and Professor Starling, F.R.S. Mr. Priestley Smith, Mr. Martin Flack, Mr. Thomson Henderson, Mr. J. H. Parsons, and others will take part.

ROYAL SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m.: Mr. A. Zimmermann.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Princes of Wales's General Hospital, Tottenham, N.).—Clinics:—2 p.m.: Throat Operations (Mr. Gillies). 2.30 p.m.: Children's Out-patient (Dr. T. B. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 p.m.: Eye Operations (Mr. Brooks). 4.30 p.m.: Lecture: Mr. H. D. Gillies: Tuberculosis of the Larynx.

BROMPTON HOSPITAL FOR CONSUMPTION.—4.30 p.m.: Lecture by Dr. B. Shaw: The Clinical Diagnosis of Occult Pulmonary Tuberculosis by means of Tuberculin.

THURSDAY, DECEMBER 5TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OBSTETRICS AND GYNECOLOGY) (1 Wimpole Street, W.).—8 p.m.: Specimens by Dr. Handfield-Jones, Dr. Beckwith Whitehouse, Dr. Williamson and Dr. Gordon Luker. Short Communication by Dr. Florence Willey. Papers: Dr. Clifford White: The Contraction Ring as a Cause of Dystocia, with Description of Specimen removed during Labour.

NORTH-EAST LONDON CLINICAL SOCIETY (Princes of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Clinical Meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Mr. C. W. Mansell Moullin. (Broadshaw Lecture).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Princes of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynaecological Operations (Dr. A. E. Gilles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chapple).

FRIDAY, DECEMBER 6TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF LARYNGOLOGY) (1 Wimpole Street, W.).—4.30 p.m.: Cases, Specimens and Instruments by Mr. C. W. M. Hope, Dr. Walter G. Howarth, Dr. Harold Whale, Dr. P. Watson-Williams, Dr. D. R. Paterson, Mr. J. F. O'Malley, and others.

ROYAL SOCIETY OF MEDICINE (SECTION OF ANÆSTHETICS) (1 Wimpole Street, W.).—8.30 p.m.: Mrs. Dickinson Berry.

MONDAY, DECEMBER 9TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Discussion on "Intestinal Stasis," to be introduced by Mr. W. Abuthnot Lane, followed by Dr. A. C. Jordan, Dr. H. Chapple, Dr. Murray Leslie, Mr. L. E. Creasy, Dr. Distaso, Mr. Barrington Ward, Dr. Schlesinger, Mr. H. Sampson, Mr. J. E. Waugh, Dr. Ofenheim, and Mr. Edred M. Corleer.

Appointments.

BEDALE, F. S., M.R.C.S., L.R.C.P., House Surgeon to Special Departments at the Manchester Royal Infirmary.

CLEMINSON, F. J., M.C. Cantab., F.R.C.S. Eng., Clinical Assistant to the Ear and Throat Department at University College Hospital.

DINGLEY, L. A., M.R.C.S., L.R.C.P. Lond., House Surgeon at University College Hospital.

DUGGAN, N., M.B., Ch.B. Vict., Senior House Surgeon at the Manchester Royal Infirmary.

LEWIS, T., M.D. Lond., M.R.C.P. Lond., Assistant Physician to University College Hospital.

MORRIS, C. W., M.R.C.S., L.R.C.P. Lond., Registrar of Anæsthetics at University College Hospital.

Vacancies.

County and City Asylum, Powick, Worcester.—Junior Assistant Medical Officer. Salary £160 per annum, with board furnished apartments, washing, and attendance. Applications to Medical Superintendent.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £150 per annum with apartments (not board). Applications to the Hon. Secretary, Mr. G. A. Lightfoot, 23 Castle Street, Carlisle.

Clare Hall Sanatorium South Mimms, Barnet.—Assistant Resident Medical Officer. Salary £120 per annum, with board, lodging and laundry. Applications to Ernest F. Collins, Clerk of the Middlesex District Hospital Board, Town Hall, Chiswick.

North Cambridgeshire Hospital, Wisbech.—Resident Medical Officer. Salary £150 per annum, with unfurnished house. Applications to William F. Bray, Secretary.

Herefordshire General Hospital.—House Surgeon. Salary £120 per annum, with board, furnished apartments, and washing. Applications to W. A. W. Pricc, F.C.I.S., Secretary, The Hospital for Sick Children, Great Ormond Street, W.C.—House Surgeon. Salary for six months £30, washing allowance £2 10s., and board and residence in the Hospital. Applications to the Secretary.

Births.

CAZENOVE.—On Nov. 25th, at West Norwood Lodge, Knight's Hill, West Norwood, the wife of W. R. Cazenove, M.R.C.S., L.R.C.P., of a daughter.

HINDS.—On Nov. 27th, at 17 Tennyson Road, Worthing, to the wife of Frank Hinds, M.D., a daughter.

HOLMAN.—On Dec. 1st, at "Galeston," Eton Avenue, Hampstead, N.W., the wife of Frank Kay Holman, M.D., M.R.C.S., L.R.C.P., of a daughter.

Marriages.

BURNETT-KENNEDY.—On Nov. 26th, at Bombay, Captain R. F. D. Burnett, 42nd Deoli Regt., eldest son of Surgeon-General W. F. Burnett, to Elinor, eldest daughter of the late T. J. Kennedy, Esq., I.C.S.

FORD-HOILE.—On Nov. 30th, at the Parish Church, Wimbledon, Frank C. Ford, M.B., of Wimbledon, to Elizabeth Stirling Burns, widow of Brigade-Surgeon Lt.-Colonel Edmund Hoile, M.D., and daughter of the late Rev. Joseph Milne, M.A., of Bathgate.

TYRRELL GRAY-WHITELAW.—On Nov. 28th, at Holy Trinity Church, Brompton, Harry Tyrrell, younger son of Richard Gray and of Mrs. Gray, of 38 Harley House, Regent's Park, N.W., formerly of Sao Paulo, Brazil, to Elizabeth Gibson Whitelaw, adopted daughter of Mrs. H. de G. Parker-Jervis, of 73 Egerton Gardens, S.W.

Deaths.

BIRCH.—On Nov. 27th, at London, Lt.-Colonel Edward Alfred Birch, M.D., F.R.C.S., Indian Medical Service, retired.

GREENHOW.—On Nov. 26th, at Esher, Surrey, Surgeon-Colonel Henry Martineau Greenhow, F.R.C.S., late H.M. Bengal Army, in his 84th year.

HOBART.—On Nov. 28th, Edith Guest, wife of N. Henry Hobart, M.B., 33, South Mall, Cork.

MURRAY.—On Nov. 26th, at the Parks, Tenbury, Worcestershire, William Berkeley Murray, M.D., eldest son of the late Hon. William Murray, of Barbados, W.I., aged 70 years.

PLASKITT.—On Dec. 1st, suddenly, Joshua Plaskitt, F.R.C.S., of 25, Chapel Street, Belgrave Square, S.W., aged 78.

SMITH.—On Nov. 29th, at Bramblecot, Kenley, Surrey, William Johnson Smith, F.R.C.S., aged 72 years.

STENMAN.—On Nov. 25th, at Leighton Buzzard, Frederick Stedman, Surgeon aged 65 years.

No. 24.

NOTES AND COMMENTS.

The Last Word.

THE problem to be voted upon by the medical profession next week has been narrowed down to a few issues.

It must be confessed that the prolonged dispute with Mr. Lloyd George has been productive of the solid, but, as many still think, inadequate additional sum of money voted by the Government, whereby the money grant has been raised to 6s. 6d. The limitation of income of the insured to £2 has not been ceded. The right of dispensing is not granted except in the case of sparsely populated rural districts. Mileage is still a standing grievance, untouched save in the case of a small fringe of country practices. As regards lay control of medical work, that most objectionable element is retained as the ultimate court, but an intervening medical board has been added buffer-wise between the two. If the profession, therefore, comes to terms with the Government under such circumstances it will be as a matter of policy and not because they have gained their cardinal points. It is impossible to forecast the issue, but clearly the terms now defined will be unpalatable to a large number of medical men. On the other hand, many others may think it wise to accept them as a matter of policy. Indeed, various associations have been formed with that express end in view, and in some cases it has been announced that a following of several thousands has been secured.

A Common Interest.

ONE of the bodies formed to further the acceptance of the Act under Mr. Lloyd George's latest conditions has gone out of its way to belittle its consultant and specialist brethren.

In a recently-issued circular it speaks contemptuously of the consultants who are not concerned in the treatment of insured persons under the Act—that is to say, as paid officials. That seems to be a poor return for the whole-hearted way in which the higher ranks of the profession have fought the common battle. It must indeed be a short memory that has lost its gratitude to Dr. Fred J. Smith for his fine stand against the Council of the British Medical Association, and for carrying through the famous Queen's Hall meeting. That gathering, if not the largest was probably the most important ever held in the history of medicine in the United Kingdom. It brought men together and inspired them with the enthusiasm of a common cause where the machinery of the Association had failed to guide, to govern, or command. Apart from gratitude there is the question of the position of the hospitals under the Act. The only logical way out of the difficulty seems to be the payment of hospital

staffs for attendance upon insured persons. Then will come the opportunity for private practitioners to help the consultants and specialists.

The Hospitals —Great and Small.

THE voluntary medical charities will have to fight their battle sooner or later over the Insurance Act. In one large hospital it has been ascertained that nearly 50 per cent. of the patients belong to the insurable, and 25 per cent. to the insured class. It is beyond the bounds of reason to expect either the hospitals or the hospital honorary staffs to treat these people for nothing. Then again, employers who are called upon to pay large sums of money under the new Act will naturally cut off their subscriptions; indeed, not a few have already taken that step. One can hardly see how the State is to escape subsidising the hospitals either out of public moneys or as a part of the necessary medical outlay under the Act. To put an end to the hospital system would be to endanger scientific medical progress, and to undermine the foundations of medical education. It is generally understood that a movement is on foot to protect the interests of the larger hospitals. Nothing has been said about the smaller hospitals, which have done, and are doing, a vast amount of scientific work of a high order. Unfortunately, the large metropolitan and provincial funds have, for some reason best known to themselves, always been hostile to the small hospitals. It is to be hoped that the Government, when the hospital question comes up for settlement, will take a broader and more judicial view of the claims of the smaller hospitals, from which no small part of the special knowledge of the general practitioner has been derived.

The Threepenny Doctor.

DR. JELLEY, who has attained notoriety as the medical man who gives medicine and advice for the modest, not to say the minute, sum of threepence, seems destined to come into public notice from time to time. It transpired at a recent inquest held at the Hackney Coroner's Court that while on his rounds one day he was called in to a young married woman who was suffering from hæmorrhage following an abortion. According to his own testimony he used two clean handkerchiefs which he was in the habit of carrying about in his pocket to meet various emergencies. The woman died ultimately of general sepsis, and the Deputy Coroner, a medical man (Dr. Guthrie) expressed an opinion that a handkerchief under such circumstances would necessarily be septic. Dr. Jelley combated that view, and maintained that it would come aseptic from the laundry. We fear that any student who advanced

such a view at his final examination would be promptly rejected. Dr. Jelley, who does things on a large scale (*i.e.*, apart from the question of fees) said he had attended 12,000 women, presumably during the ten years he had been in practice. At threepence a head that means £125. It is that kind of practice apparently which forms the basis of the actuarial calculations of the friendly societies.

WE commented in this column a few weeks ago (MEDICAL PRESS AND DR. COX AND CIRCULAR, November 13th) on the the Medical speech which the Rt. Hon. Dr. Profession. Michael Cox had delivered to the last meeting of the Irish Advisory Committee. We read the speech as a repudiation of the policy adopted by the medical profession of Ireland in reference to the Insurance Act and to the friendly societies. The same interpretation was put on it by members of the friendly societies, some of whom hailed Dr. Cox's utterances as the first signs of a cleavage in the ranks of the profession. We learn now that we and they and everyone else have misunderstood Dr. Cox. A correspondence on the subject which has taken place between the honorary secretary of the Dublin Local Medical Committee and Dr. Cox is reproduced below. Dr. Cox is amazed at the misconstruction put upon his words. It appears that his hard words were meant not for his colleagues but for their critics. We are willing to accept all this—the matter is of no importance except to Dr. Cox himself. He, however, makes no attempt to explain away the really important element of his speech—the suggestion that in Ireland dependents of the insured person should be entitled to the medical benefit. This simply means that a medical man in Ireland should attend on a family for the same fee as his colleague in England would receive for one individual.

Drunkness Off Duty. THE question as to whether employers of labour have the right to exercise any sort of jurisdiction over the private life of their employees has caused much agitation among the railwaymen in the North during the last few days. On Monday night last it was estimated that some 5,000 men were idle upon the North-Eastern Railway system, the origin of the strike being primarily due to the reduction in rank and wages of a driver owing to his conviction for being drunk while he was off duty. The situation is not without great medical interest. No one would condone such an offence for a single moment in any official responsible for the lives of hundreds of human beings had it occurred when he was aboard his engine. The point is whether a man becomes *ipso facto* a worse engine-driver for being guilty of intoxication after hours. An employee is generally supposed to be absolutely free to do what he likes when he is off duty, and he may ruin himself in any way that he chooses provided that he still remains fit for his daily work, though if he be wise he will not voluntarily indulge in any habit that will impair his capacity as a wage-earner. The opinion of many large firms, including that of the North-Eastern Railway Company, appears to be that "drunkenness, even off duty, is an unpardonable offence," these words having once been used by a well-known Board of Trade inspector. It is pretty well established that repeated bouts of intoxication would, by degrees, lead to some impairment of the higher nerve-centres, resulting in a lessened capacity for enduring any position of great physical or mental strain. Hence, the action of the railway company is, at any rate, upon the side of public safety.

LEADING ARTICLES.

MEDICAL BENEFITS AND THE INSURANCE ACT.

IN spite of some further advance in negotiations between the Chancellor of the Exchequer and the British Medical Association, as representing the medical profession of the United Kingdom, the matter of the administration of the medical benefits under the National Insurance Act is by no means settled. This lack of finality, occurring as it does within a month of the coming into operation of the benefits in question, presents an extraordinary and indeed an unprecedented legislative situation. As things stand at the present moment, however, a final decision must be arrived at before Christmas. The chief points urged by the recent deputation upon the Insurance Commissioners were, according to a memorandum issued by the latter body, as follows:—(1) That the duties of practitioners under the Act should be more clearly defined; (2) that the matter of remuneration, night visits and mileage should be given special consideration; (3) that medical men under the Act should be free from lay control. These points have been met partially by small concessions from the Government, and it now remains for the majority of the profession to say whether they are or are not to be accepted. The modifications thus offered may be thus summarised:—(1) In a disputed case a doctor should appeal to local Medical Committee, with final appeal to Court of Referees. (2) Insurance Committees to have power of fining or suspending from medical benefit insured persons who make unreasonable demands upon the doctors. Small special fund for extra payment to doctors where travelling difficulties arise. (3) Medical members of each Insurance Committee to constitute not less than one-tenth of the committee. Before doctor is struck off panel Insurance Commissioners to be advised by a medical committee of inquiry. Slight alteration in composition of sub-committees appointed to hear complaints against doctors. Then, in addition, medical practitioners are permitted to dispense medicines when the patient resides in a rural district more than a mile away from a chemist who is on the panel. With regard to these concessions it may be said at once that some of them are of a meagre and unsatisfactory nature. That which refuses a fair mileage rate for long journeys is tolerably certain to be a source of friction in actual practice. What reasonable excuse can there be for not paying a practitioner for the extra time and outlay involved in long journeys? In what other profession would a flat rate of an analogous kind be tolerated? Mr. Lloyd George may be asked to consider the charges made by a solicitor for visits, say, to a client's house, to another solicitor, to various law courts, and so on—visits that involve varying distances and varying amounts of time—what would the legal profession say to the statutory imposition of

a single, fixed, and inadequate fee for all such services? Put in that way the proposition sounds grotesque, yet it does not remotely differ from the attitude of the Chancellor of the Exchequer in his well-meant efforts at vicarious State philanthropy, the brunt of which he has attempted to cast upon the shoulders of an already over-burdened profession. The strength and validity of the criticisms that have been raised against the proposals of the Act are now familiar, and little would be gained by going over the ground again. The latest concessions of Mr. Lloyd George are to be regarded as final. December 31st has been fixed as the latest day on which acceptance of the Insurance Committee's offer can be tendered. There is ample time left under that arrangement for carrying out a referendum to the profession. Meetings have been called for that purpose in all the divisions of the British Medical Association and non-members invited to attend. Votes will be received at the head office in London not later than Wednesday, December 18th, and will be counted on the following day. A special representative meeting of the Association will meet on Saturday the 21st. Whatever the result, the Christmas of 1912 is likely to become famous in the annals of medical history in the United Kingdom. In a crisis like the present it is out of the question to advise strongly upon any definite course to be adopted. It must be left to the individual medical man to vote one way or the other according to his convictions, and after that to abide by the decision of the majority. Failing such union the prospect is of a kind that may well fill the most optimistic medical observer with apprehension. Already various organisations have been formed with the avowed intention of working the Act under the latest conditions independently of the views of the majority of their fellow practitioners. No surer road to disaster could be imagined than that which lies in the direction of divided counsels at the very moment when the final blows are being exchanged and victory turns in the balance. It would be indeed a sad ending to a gallant fight were any considerable number of our men at the last moment to go over to the enemy, nor can such a result be regarded as constituting even a probable contingency.

CURRENT TOPICS.

Hospital Decentralisation.

WITH the removal of many of the old landmarks and the change in the character of the residential population of central London, it is not surprising that the large hospitals situated in or near this area should move literally with the times. When King's College took the lead in this direction it was felt at the time by those who were sufficiently far-seeing that the example of this great institution would inevitably be followed by others sooner or later. The authorities of Westminster Hospital are now promoting a Bill in Parliament next Session en-

abling them to sell the present building and site in Broad Sanctuary and to buy or lease another site in the county of London and rebuild the hospital thereon. The necessary powers are also taken for dealing with the Westminster Hospital Medical School, the Westminster Training School and Home for Nurses, and the Incurable Fund. The incurable cases are to be accommodated either at the new hospital, or elsewhere, as may be found expedient. It will, of course, be necessary to repeal in whole or in part the Westminster Hospital Act, 1836. We understand that although a possible site for the new hospital has been considered, no definite decision on this point has yet been reached. The present building was erected in 1834, and was extended in 1886-7, and 1900-1. It claims to be the oldest hospital in London supported by voluntary contributions. Another institution that is shortly contemplating removal is the British Lying-in Hospital, which proposes to amalgamate with the Home for Mothers and Babies, Woolwich, under the combined title of "The British Hospital for Mothers and Babies." The sub-title of the latter institution, "National Training School for District Midwives," will be retained, and the joint hospital will occupy a new building which is shortly to be erected at Woolwich for the purpose. The usefulness of this hospital will be materially increased by following the population to the outskirts of London, where it hopes to assist the Woolwich home in realising the primary object of its existence.

The Bradshaw Lecture on Tumours.

AT the annual Bradshaw Lecture, before the Royal College of Surgeons, on Thursday last, Mr. C. W. Mansell Moullin chose for his subject "Tumours," which he described as being of two kinds, those which spring from germ cells and those from somatic cells. The origin of tumours he dated back almost to the beginning of all things, if not actually to that time when life made its first appearance upon earth, at least to a period so immeasurably remote that it is not in the power of our minds to form a conception of its distance. They arose when the Metazoa came into being, when for the first time the daughter cells of some primitive organism, failing to separate from each other after the parent had divided, gained the advantage of combination over their fellows, and founded the new kingdom. There has been no change since. The laws that regulate the development of *Homo sapiens* now are the same as those that regulated the development of the Hydra or its representative then. "Tumours are not inherited," said the lecturer, "though certain families are more prone to the formation of tumours than others. The power of hereditary transmission varies in strength in different families. In some the hereditary power is so strong that they maintain throughout life the full perfection of their development, and growth is never allowed undue licence. In others the power is weaker, and fails to a greater or lesser degree. It is not that the tumours are

inherited, but the strength of the driving force that directs development and controls growth." With regard to amputation, it was stated that, though this might free the patient from the consequences, it cannot be regarded as a cure for the growth of tumours. All hopes of finding a cure must rest either upon the discovery of some remedy which can directly kill the tumour cells without endangering the vitality of the normal tissues, or upon stimulating to increased energy the animal tissues that surround the tumour, until they are able to treat those degenerate tumour cells in the same way that the workers treat the drones.

State Aid for Insanity.

A CONFERENCE was held last week at the Guildhall of representatives of asylums in England and Wales in order to consider the possibility of obtaining State aid for scientific research in mental diseases. As the chairman, Mr. Morgan Thomas, Lord Mayor of Cardiff, remarked, grants are often given by the Local Government Board for research work in the case of other diseases, and there appears to be no reason why this should not also be done in the case of mental disorders. Individual effort, though capable of accomplishing much that is of permanent value, cannot be expected to cope with the large amount of work that calls for scientific investigation upon a more extensive scale up and down the country. In the direction of pathological research into mental disease, Cardiff has always been well to the front, and in one of the institutions under the control of the London County Council many valuable reports, to which we alluded last week, have emanated from its pathological laboratory. Nevertheless, a great need exists for the wider recognition by the State of the claims of the insane in the direction of grants towards research for the prevention, cure and treatment of mental diseases. It is understood that a deputation will be appointed shortly to wait upon the Lunacy Commissioners and the Home Secretary.

The Cleansing of Dublin.

RESIDENTS in Dublin were interested to learn last week from full accounts in the daily papers that a new method of street cleansing was on trial, which was expected to banish mud from the city famous for its dirt. The Cleansing Department were in fact trying the effect of hosing the streets. The method is so expensive, however, that it can only be applied to the principal thoroughfares, so that we must not expect any real decrease of the dirt in the back streets. In Dublin street dirt is a very inclusive term—it is not merely the grit of the stone pavements, but also horse droppings, cattle droppings, human sputa and faeces, decaying vegetables, putrid fish and offal of every description. By a curious coincidence, at mid-day on the very day that the Dublin papers were hailing the new departure, the gutter of one of the main thorough-

fares of the city—recently re-named in honour of one of the greatest of modern Irishmen—was blocked for some twenty yards by a heap of fish offal lying overnight from the previous day's street market.

The Rounded Corner.

IT is always interesting to note the influence of scientific ideas upon the style and character of modern building construction. More light and air space are, as a rule, provided for in all up-to-date dwellings, while heating arrangements and sanitary fittings of even small houses have greatly improved during the last few decades. It is hospital architecture, however, to which one naturally looks to find practical examples of the latest hygienic devices. When the principles of asepsis were once recognised all corners and angles began speedily to disappear from operating theatres and surgical wards, for all such dangerous nooks were felt to be lurking-places of pathogenic germs. The proper cleansing of any room or ward in which these objectionable features have not been removed is almost an impossibility, for ordinary scrubbing-brushes cannot reach the interstices and angles at the junctions of the walls with the ceiling and floor. Even the modern vacuum cleaner fails at this critical point, because some of the dust may have become caked and adherent. Public staircases, especially those to and from railway stations, should always have their corners rounded in order to facilitate cleaning. At one of the Metropolitan Railway stations this was recently done, not for hygienic reasons—alas! as inquiry proved, but in order to prevent fire from the accidental ignition of unused matches getting in between the wood-work. The rounding of the corners between each step would surely serve both purposes.

The Futile First-Aider.

ONE of the associations of nurses has been tilting against a Red Cross Association on the grounds that the latter sent ambulance sections to the Bulgarian War which included nurses who were not properly qualified as such. The amateur first-aider is often the cause of a great deal of trouble. It would certainly be a good thing if there was always a bystander competent to render efficient first-aid on the occurrence of those accidents and emergencies that so frequently happen. As a matter of fact, there is usually some one present who thinks he fulfils these conditions, and who is often the cause of considerable harm to the sufferer, either by his neglect or his activity—usually the latter. It is very rare to find anybody who has attended a course of first-aid lectures and is willing to leave well alone. If there is a broken leg he, or she, must borrow onlookers' umbrellas and proceed to set it. Angels rush in where even fools would fear to tread, and the net result is increased suffering to the patient and increased work for the surgeon when he eventually rescues the case. Every amateur

ambulance worker knows all about the theory of the tourniquet and applies it in season and out of season. If a tourniquet were as harmless as it looks the applicator would be happily conscious of good work well done and no one a penny the worse. Unfortunately for him in most bleeding wounds the injury is to one or other of the superficial veins. A tourniquet is applied with a pressure nicely estimated to leave the arteries free from pressure while venous return is effectually obstructed. A completely ignorant man would probably tie something over the bleeding point and stop the hæmorrhage; the man who has attended lectures exclaims with Bottom "This is Eracles' vein" and proceeds to deal with it with the confidence born of ignorance. The root of all this evil is that the layman, however willing and however skilled at adapting triangular bandages to inaccessible places, has seen very few accidents. Before he is allowed to practise on the streets he should attend the accident department of a hospital and learn rough diagnosis. As it is he has treatment at his finger ends, but requires someone to tell him what the matter is before he can make efficient use of his knowledge. When his diagnostic skill is on a par with his other information he will learn the most important thing of all—when to apply to a case a policy of masterly inactivity.

Creative Art and Sex Emotion.

CHAUCER noticed that in the spring "smale foules maken melodie . . . so priketh hem nature in her corages." The male bird sings his sweetest song and puts on his brightest plumage at the time of year when he goes a-courting. He does all this to attract the female, though perhaps he is not conscious of it and thinks that his song is an inevitable expression of the *joie de vivre* that courses through his veins, but seen objectively, it is merely one of Nature's ways of keeping up her idiosyncrasy for preserving the race at all costs. Anyway, the bird sings his song—a creative act of a high artistic order—during the annual period of sexual activity. This period alternates with a longer one during which male and female live together in a practically asexual state and then the sex song is never heard. In the human race sex-feeling exists persistently through the whole period of sexual life, and, like the birds, the human male expresses himself in creating colour and music. A superior creative instinct is as characteristic of the human male being as is the song of the male bird, but as men and women are in the plane of pure intellect often absolutely equal, so we get occasionally a tendency to desexualisation, male showing female tendencies and *vice versa*, and these cases supply us with exceptions to the rule. Still, on the whole, in the spheres of pure art, the male is creative, and the female appreciates the creation. Even where we find the female assuming the function of originator the work has usually a more superficial appeal than that of the male; it may show qualities of grace, dexterity, and a light beauty, but seldom or never

does it possess the sense of power and the deep appeal of the best male art. Of course, this is a difference of kind, not of degree. Women have an intenser appreciation of men's art than any man. And the sum total of the whole matter is that Nature wants the race to continue—"so careful of the type she seems, so careless of the single life." All around us and all the time Nature fights for the eternal preservation of her precious germ-plasm.

PERSONAL.

H.M. THE KING has been graciously pleased to sanction the following promotions in, and appointments to, the Order of the Hospital of St. John of Jerusalem in England:—To be Knight of Grace, Major Arthur William Mayo-Robson, C.V.O., F.R.C.S., R.A.M.C. (T.F.). To be Esquires, William Disbrow Brydone-Jack, Esq., L.R.C.P. and S.Edin., and Thomas Nelson, Esq., M.D. (from Honorary Associates).

DR. EUGENE M. NIALL, M.D., has been appointed Honorary Physician to the Westminster General Dispensary.

MR. J. EVERIDGE, F.R.C.S., has been appointed Sambrooke Surgical Registrar at King's College Hospital.

DR. MARY COGHILL HAWKES has been appointed Superintendent of the Physical Exercise and Massage Department at the Royal Free Hospital.

MR. R. BESWICK, B.Sc., M.R.C.S., L.R.C.P., was admitted last week by the Bishop of Willesden at St. Paul's Cathedral as a parochial reader to St. Botolph, Bishopsgate.

DR. HAROLD KERR has been appointed Medical Officer of Health of Newcastle in succession to Dr. Henry G. Armstrong, who recently retired after forty years' service.

DR. F. E. FREMANTLE, Medical Officer of Health for Hertfordshire, has been selected as one of the Unionist candidates for the Parliamentary representation of Stockport.

CAPT. H. B. SCOTT, I.M.S., has been appointed to officiate as Police Surgeon and Pathologist to the Rangoon General Hospital, in place of Captain H. A. Dougan, deceased.

THE State Medicine Syndicate of the University of Cambridge have appointed Dr. Humphry, Dr. Myers, and Professor Sims Woodhead to be members of the Managing Committee for the Diploma in Psychological Medicine for three years.

MR. WASHINGTON EPPS, M.R.C.S., L.R.C.P., Physician to the London Homœopathic Hospital and a Fellow and former President of the British Homœopathic Society, left estate valued at £36,948 gross, with net personalty £36,644.

At the forthcoming International Congress on Agriculture which is to be held next June at Ghent during the great International Exhibition, Dr. H. B. Newham will represent the London School of Tropical Medicine in the British exhibit at the Exhibition, and Dr. J. W. W. Stephens the Liverpool School. Sir A. M. Branfoot and Dr. Andrew Balfour, of Khartoum, will deal with the plague and Eastern diseases.

A CLINICAL LECTURE

ON

SOME THERAPEUTIC POINTS.

By HERBERT FRENCH, M.A., M.D.Oxon., F.R.C.P.Lond.,

Assistant Physician, Pathologist and Lecturer, Guy's Hospital, London.

(Concluded from p. 596.)

Turning now to a totally different condition, I should like to refer to

THE RAPID CURE OF PNEUMOTHORAX BY PARACENTESIS CONTROLLED BY X-RAY OBSERVATION OF THE CHEST DURING THE OPERATION.

I am speaking particularly of cases in which the pneumothorax is associated with relatively little disease in the lung itself, generally an early stage of apical phthisis. Patients of this kind are not common, but most of us meet with one now and then. It is good practice, as a rule, to leave the air in the pleural cavity for some weeks at least after the onset of the pneumothorax and this for two reasons, namely, first, that by keeping the lung thereby at rest the tuberculous process within it is assisted in its healing—indeed, the rather drastic measure of inducing pneumothorax artificially in the treatment of phthisis that is not advanced is adopted regularly by some authorities; and, secondly, because if one attempted to remove the air from the pleural cavity by paracentesis soon after the onset of the pneumothorax the hole in the lung through which the air originally escaped into the pleural cavity would probably not have healed over sufficiently to prevent its reopening under the strain of paracentesis. In four or five weeks, however, if the pneumothorax persists, instead of the air being spontaneously absorbed, there is a danger that the collapsed and compressed lung will become so fibrosed that it never will re-expand properly if active measures are not taken to cure the pneumothorax. When pus is present at the same time it is generally good practice to treat the condition as one would an ordinary empyema without a pneumothorax, and resect a rib for drainage of the chest. When air is present in the pleural cavity without fluid, however, or with only a small quantity of serous fluid, it is sometimes possible to cure the pneumothorax rapidly by paracentesis assisted by the X-rays. One of the first cases so treated is recorded by Dr. John Fawcett in the Guy's Hospital Reports for 1907, Vol. lxi., p. 49.

One uses the ordinary paracentesis trocar and cannula attached to the vacuum bottles that used to be employed in ordinary paracentesis of fluid. It is important to have two or three of these ready exhausted, and I am strongly in favour of the use of a powerful foot-pump for the purpose, because the smaller hand-pumps are so frequently inefficient. The patient either sits or lies, according to the circumstances of the case, and the exact position of the heart and of the compressed lung is observed by means of the X-rays and the fluorescent screen. The situation and the extent of the pneumothorax show very clearly as a rule. One inserts the trocar and cannula in the ordinary way, watching the contents of the thoracic cavity on the X-ray screen to ensure that the needle is well within the cavity of the pneumothorax and that it does not strike the lung beyond. On now opening the tap of the vacuum bottle the air is drawn out from within the pneumothorax in exactly the same way that fluid is in the case of a hydrothorax, and one

can regulate the rate at which it is thus evacuated by varying the degree to which the tap of the exhaust bottle is opened. The patient experiences very little discomfort, though he will presently begin to breathe more rapidly and say that he has a curious sensation, generally not acutely distressing, within his chest. One can see the compressed lung expanding as one watches it on the X-ray screen and the heart can be watched coming back towards its normal position; as the lung is sucked out towards the end of the cannula, the latter is slowly withdrawn and the direction in which its inner end is to point in order to draw out the last of the air can be observed easily on the X-ray screen. If the original hole in the lung through which the pneumothorax occurred has healed over so that air no longer escapes from the lung into the pleural cavity, it is possible in this way to draw off practically the whole of the air that has been in the pneumothorax, to re-expand the compressed lung until it again occupies its right position, and to restore practically to normal, except, of course, for the tuberculous or other disease in the lung itself, that which a quarter of an hour or twenty minutes previously was a serious pneumothorax. No anæsthetic is required. When all the air has been exhausted, the cannula is simply drawn cut, and owing to the way that the skin and the subcutaneous parts move upon one another there is no danger at all of fresh air escaping in through the chest wall from outside. It is not even necessary to apply a dressing. The simplicity of the treatment is as striking as is the benefit it gives.

The next point that I shall refer to is perhaps rather a prognostic than a therapeutic point, but seeing that when one is able to measure the significance of a symptom in a given case the treatment that will be adopted is also liable to vary considerably, I may be permitted perhaps to include it here; it concerns

THE VALUE OF ESTIMATIONS OF THE UREA IN THE BLOOD IN CASES OF ALBUMINURIA.

Probably in the case of no symptom is it more difficult to assess the degree to which it matters than it is in connection with albuminuria. Not only is one familiar with the transient intermittent albuminuria of young men and women who require absolutely no treatment for it at all, but one also knows that there are cases of organic albuminuria in people suffering from chronic nephritis in which the patients survive for fifteen or twenty years after they have refused altogether to observe any particular precautions as regards proteid dietary, medicinal treatment and things of that kind, whilst other patients who have not seemed to be so ill as this have nevertheless died with almost unexpected rapidity. It is exceedingly difficult to be able to pick out by physical signs alone those patients in whom the albuminuria matters, and indicates the need for strict treatment, from those other cases in which, notwithstanding the presence of albuminuria even with renal tube casts and a raised blood pressure, the best treatment is not to insist upon any drastic departure from the ordinary way

of living, provided the patient avoids things that are obviously unhealthy.

Again, in the case of elderly men suffering from consecutive nephritis the result of enlargement of the prostate, it is really not at all easy to be sure how good or how bad the kidneys are, and therefore to what extent it is worth while resorting to radical cure by removal of the prostate. There are, of course, many different measures now employed to test the renal efficiency; most of these are based upon the oral administration or the injection into a vein of some substance which is excreted by the kidneys and can be detected in the urine—methylene blue, for instance; but even when one has employed these tests one is very often left in considerable doubt as to whether the excretory powers of the kidneys are adequate or not. It used to be held that estimation of the total urea in the urine afforded a measure of the renal efficiency, but from metabolism work done many years ago now, in conjunction with Dr. J. A. Butler, I am sure that the urea excretion in these cases runs almost parallel with the nitrogen taken by the mouth, and that it is only when the patient is so ill as not to be able to take much proteid food that the total urea in the urine falls markedly below the normal minimum. In patients who look well, but who nevertheless have inadequate kidneys the urea in the urine may reach a very fair total, and one may draw a very erroneous conclusion as to the renal adequacy from the results of urinary urea analysis. There is, indeed, no single criterion of renal adequacy, but I should like to draw attention to a new one, which is likely to be employed fairly widely, and this is the determination of the urea in the patient's circulating blood. In ordinary healthy persons the urea in the blood amounts to something between 10 and 15 parts per 100,000. In cases of serious renal mischief, whether "consecutive," or of the Bright's disease type, or the result of calculous or tuberculous disease, this figure frequently rises to as much as 150 or 200 or 250 parts of urea per 100,000 parts of blood, whilst in rarer instances the figure reaches as much as 500 parts per 100,000. It would be difficult to lay much stress upon a merely small rise above the normal 10 or 15 parts per 100,000, and when one meets with figures such as 20 or 25 parts per 100,000 it does not follow that the kidneys are inadequate. When the figure rises to 75 or 100 parts per 100,000, however, this is a sign of danger, and figures that are higher still are signs of graver omen. Dr. J. H. Ryffel and I have now investigated a large number of patients in respect to this point and the above conclusions are definite. The converse is not necessarily true, for in some cases of puerperal eclampsia, for instance—but not of ordinary uræmia—the urea figure in the blood has been little increased; this supports the view that eclampsia is not due primarily to the inadequacy of renal excretion, but is the result of the formation in the body of abnormal metabolic products, apparently in consequence of pathological changes that take place in the liver as the result of the renal disease. The usefulness of urea estimations in the blood in helping to pick out those cases of cystitis and enlarged prostate that are suitable for operation from those in whom the consecutive renal changes have gone too far is obvious. Some patients with severe pyuria and frequency of micturition may seem to be in too serious a condition for removal of the prostate to be justifiable, and yet, other things being equal, if the urea in the blood is not increased this affords an argument in favour of operation; whilst if the urea is much increased then the clinical evidence afforded against operation by other symptoms and signs is confirmed.

The actual estimations cannot be done by one-

self in ordinary practice, but they are relatively simple if the necessary blood is sent to a laboratory where the apparatus required for its analysis is all ready to hand. One takes about 20 cc. of blood from a vein in the arm by means of a hollow needle and an all-glass antitoxic syringe in precisely the same way that one obtains blood for making bacteriological cultivations. One uses the sphygmomanometer bag as a tourniquet in the way that I shall describe later on; when the veins are standing out prominently and the skin over them has been sterilised the sharp antitoxic needle attached to the all-glass syringe is plunged directly into the median basilic or the median cephalic vein; the pressure of the blood itself fills the syringe, and in this respect the all-glass variety has a great advantage over other sorts; all bleeding stops as soon as the pressure round the upper arm is released; the contents of the syringe are expelled into absolute alcohol, about 100 cc. in a suitable glass bottle; the latter is then corked and sent in a protecting tin to the laboratory. The principles of the analysis are as follows: The absolute alcohol precipitates the serum albumin, serum globulin and fibrinogen, but takes into solution the urea together with certain other extracts. The amount of absolute alcohol used need not be measured with absolute accuracy, though it is essential to know the exact quantity of blood. On filtering and washing the filter carefully the filtrate contains the urea; it is evaporated to dryness and the residue redissolved in distilled water. The urea goes into solution; along with it there are minor quantities of other nitrogenous substances no doubt, but for clinical purposes, at any rate, the estimation of the urea by the sodium hydrobromite method, using the original *technique*, gives a sufficiently constant figure when successive samples of the same blood are analysed to warrant one in making use of the results as a numerical measure of what may be called for short the urea in the blood, though probably, just as in the case of the urine, the figure obtained represents the urea plus small quantities of nitrogen from other substances. Dr. Ryffel and I are looking forward to publishing the full results of our investigations in due course, but it will probably take several years before we obtain all the statistics we should like from a long series of cases that have been followed through from the time of the first analysis until the final result of the case is known. We already know, however, that the *technique* is simple, that the patients experience practically no discomfort beyond the initial needle-prick in the performance of the test, and that the figures obtained do afford very material assistance in interpreting the degree to which the symptom—albuminuria—signifies.

The last point that I will mention to you to-night concerns

A SIMPLE METHOD OF VENESECTION WITHOUT INCISION, BY MEANS OF A SHORT HOLLOW NEEDLE OF WIDE BORE; ALSO THE VALUE OF THE SPHYGMOMANOMETER AS A TOURNIQUET.

It may be urged that venesection is so seldom required that it does not need discussion. I think, however, that whereas formerly it was performed to so riotous and unnecessary an extent that it went entirely out of fashion when the reaction against it set in, there are, nevertheless, a considerable number of conditions in which it is not merely a useful but actually an advisable part of the treatment. It is probable that every year each of us meets with several cases in which venesection ought to be performed. To mention one or two such conditions only, venesection is of immediate benefit in cases of acute dilatation or over-distension of the right ventricle from any cause, whether

This is due to organic valvular disease of the heart, such as mitral stenosis, or to obstruction in the pulmonary circulation, such as may result from chronic bronchitis and emphysema, or from fibroid lung with or without bronchiectasis; or to renal mischief or arterio-sclerosis with high blood pressure; or to weakness of the heart muscle itself, owing to fibroid changes in it, or to flabbiness from fatty change, or to acute myocardial degeneration from acute rheumatism, pericarditis, or other similar cause. Again, venesection is undoubtedly beneficial in the treatment of acute uræmia, whether this is due to acute or chronic Bright's Disease or to puerperal eclampsia. Lobar pneumonia in vigorous young adults with plethoric tendency, if it is associated with congestion and cyanosis, frequently demands venesection, and the result of the treatment often brings refreshing sleep and relief to the patient's distress. Venesection is beneficial, again, in certain cases of cerebral hæmorrhage; in the relief sometimes of angina pectoris; in the treatment of corresponding abdominal attacks, now generally spoken of as angina abdominalis; it is even probable that small blood-lettings at intervals of a month, six weeks, two months or three months are beneficial to certain full-blooded individuals, especially males who live well without taking a sufficient amount of exercise, and who have a tendency to degeneration of the arteries and kidneys. Similar repeated blood-lettings also prove beneficial to those who suffer from buzzings in the head, attacks of giddiness, and other cerebral symptoms of arteriosclerosis associated with high blood pressure. The reason why venesection has gone so much out of fashion is largely, I think, the fact that we do not like to make incisions for the purpose, such incisions requiring careful aseptic dressing; whereas formerly the mere lancing of a vein was regarded as of no particular moment, since the days of asepsis and antisepsis have come in a skin incision is regarded with greater respect. I find, however, that it is, at any rate in many cases, a far simpler thing to remove blood by *vene-puncture* than it is by *vene-section*, and I have done so now in many cases by means of short, stout, hollow needles, made for me by Messrs. Down Bros. (Fig. 1).

FIG. 1.—The venesection needles, actual size.

Each is 2 millimeters in diameter, and the most convenient length 2 centimeters; though it is wise to have a longer one of four centimeters also in case one has a very stout arm to deal with. I find, moreover, that the use of the sphygmomanometer which Messrs. Down Bros. make for me greatly facilitates the operation (Fig. 2). The rubber bag being applied round the arm, one pumps the air until one can no longer feel the pulse at the wrist. The point at which the pulse ceases to be palpable gives

a measure of the maximum systolic blood pressure indicated by the height of the mercury column in the manometer tube. Suppose this to be, we will say, 125 mm. Hg. one can now let out a little of the air until the pressure in the manometer reaches say, 110 mm. Hg. The pulse can then be felt beating strongly, but the veins are still completely obstructed. Having cleaned the skin over the median cephalic or median basilic vein, according to which is the larger, one now simply plunges the

FIG. 2.—To illustrate the use of the sphygmomanometer as a tourniquet, and the mode of venesection by means of a short, stout, hollow needle.

hollow needle directly into the vein, the point being directed downwards towards the hand, and not upwards towards the heart, as is the general rule in taking blood for ordinary blood cultures. The reason for directing the point of the needle downwards towards the hand is that to obtain a large quantity of blood, such as 16 ounces or more, it is better for the blood in the veins to enter directly into the open end of the needle than the reverse way; the point should, therefore, be inserted in the direction opposite to that of the ordinary blood flow in the vein. The advantages of the needle being short and of big bore are: first, that from the shortness of the tube the latter does not become blocked by rapid clotting within it, a trouble which is apt to affect the longer needles of smaller bore that are generally used for obtaining blood cultures; and, secondly, that the rate of outflow of the blood into the receiver is so much more rapid that the venesection can be completed to the extent of 12 or 15 ounces in between five to ten minutes, whereas it takes a much longer time than this for the same amount of blood to flow through needles of smaller bore. As soon as the required amount of blood has poured out from the needle, the air within the sphygmomanometer bag is released; the flow of blood from the veins back into the heart at once reduces the pressure within them to a very low figure, and on withdrawing the venepuncture needle no further bleeding occurs. If a few drops still tend to ooze up from

the puncture, these stop at once if the arm is raised above the patient's head. It is as well to apply a little boric acid powder to the spot, but no dressing is required. The only difficulty arises in the case of patients in whom the superficial veins are very small. Upon the whole, however, such patients do not require venesection. It is chiefly when the arteries are relatively empty and the veins too full that venesection is required and in such patients the girth of the median cephalic or median basilic vein is so great that the needles mentioned above enter them with the greatest ease. So simple, indeed, is the letting of blood by venepuncture in this way, with the use of short hollow needles with large bore, associated by the use of the sphygmomanometer band that I am accustomed to let blood in high tension individuals and others of a similar nature in my own consulting room, the patient being so little incommoded that after it he proceeds straight to his business as if nothing had happened.

I think that many of us who might hesitate to perform the operation if cutting through the skin with a scalpel were essential, need no longer hesitate in suitable cases when the hollow needle and the sphygmomanometer are to hand.

NOTE.—A *Clinical Lecture* by a well-known teacher appears in each number of this Journal. The lecture for next week will be by F. C. Purser, M.D., F.R.C.P.I., Assistant Physician, Richmond, Whitworth and Hardwicke Hospitals. Subject: "Bulbar and Pseudo-Bulbar Paralysis."

ORIGINAL PAPERS.

THE NEUROLOGY OF THE VISUAL SYSTEM.

A Short Series of Original Papers.

By HARRY CAMPBELL, M.D., F.R.C.P.;

Physician to the West End Hospital for Diseases of the Nervous System.

PAPER IV.

THE VISUO-MOTOR SYSTEM.

THE VISUAL MUSCLES.

The muscles of the visual apparatus consist of three sets: the intrinsic, the extrinsic, and the protective muscles of the globe.

The Intrinsic Muscles of the Globe.—The iris and the ciliary muscle. The function of the iris is to regulate the amount of light entering the eye. It consists of two muscles: the irido-constrictor or sphincter pupillæ, and the irido-dilator, or dilator pupillæ. Both are embedded in the posterior portion of the iris. The constrictor is the more developed of the two. It consists of concentrically arranged fibres forming a ring immediately around the margin of the pupil. The dilator consists of radially-disposed fibres passing from the outer border of the iris to the pupillary margin, where they blend with the sphincter.

The function of the ciliary muscle is to regulate the curvature of the lens in such wise that the image of objects fixed at varying distances shall fall neither in front of, nor behind, but exactly upon, the retina.

The Extrinsic Muscles of the Globe.—The recti (superior, inferior, internal, and external), and the obliqui (superior and inferior). Their function is to secure "fixation" of objects looked at, *i.e.*, so to rotate the globes that the prolongation of each visual axis (visual axis-line from macula to a point in the pupil a little to the inner side of, and below, its centre) (*a*) shall meet at any desired point

(a) In the shortened or lengthened eye it may pass a little outside or inside this. In such cases there may in fact be slight strabismus.

in the visual field: the point fixed is thus imaged upon each macular region where vision is most acute.

The Protective Muscles of the Globe.—The orbicularis palpebrarum, the levator palpebræ, the frontalis (which assists the levator), and the corrugator supercilii. The function of these muscles is to moisten and cleanse the exposed portion of the globes by rhythmic blinking, and to protect them from violent injury and from too strong light.

THE VISUO-MOTOR NERVOUS SYSTEM.

The visuo-motor nervous system arises in the cortex (figs. 20-21) of either hemisphere from two widely separate regions—an anterior, situated in the frontal region, and a posterior, situated in the neighbourhood of the angular gyrus and the occipital lobe. From this dual origin fibres pass, having first decussated, to supra-nuclear centres situated in the upper part of the brain-stem. Thence a second series of neurons pass to the nerve nuclei, whence the oculo-motor nerves arise.

It will be convenient to consider these various stages of the visuo-motor tract in their inverse order, *i.e.*, from the periphery centrewards. Thus: *a* the nerve supply of the visual muscles, *b* their nuclear centres, *c* their supra-nuclear centres, *d* the cortico-fugal supra-nuclear paths, and *e* the cortical centres.

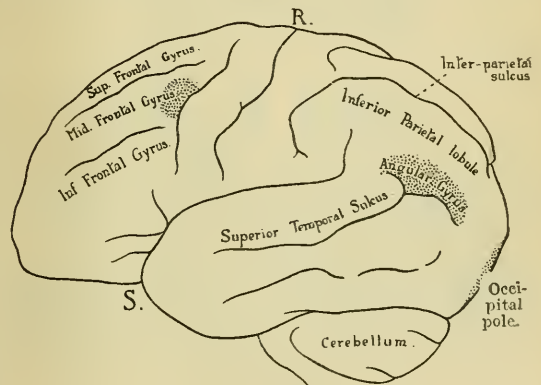

FIG. 20.—R. Fissure of Rolando. S. Fissure of Sylvius.

The inter-parietal sulcus separates the superior parietal lobe above from the inferior parietal lobe below. The angular gyrus borders the posterior extremity of the superior temporal sulcus. The shading represents areas on the exposed surface of the cerebral hemispheres, stimulation of which produces movements of the globe (and lid)—*i.e.*, the posterior portion of the middle frontal gyrus, the lower part of the inferior parietal lobule, notably the region of the angular gyrus, and the occipital pole. Grasset suggests that in the latter case the stimulus passes to the angular gyrus. It has, however, to be remembered that efferent fibres are known to pass from the peri-calcarine hemiopic cortex to the brain-stem.

a. The Nerve Supply of the Visual Muscles.—The ciliary muscle: third nerve. The irido-constrictor (sphincter iridis): third nerve. The irido-dilator: sympathetic.

Extrinsic muscles: all by the third nerve, except the external rectus and the superior oblique. The former is supplied by the sixth, the latter by the fourth. The levator palpebræ: the third. The unstriped fibres of the levator palpebræ: the sympathetic, which also supplies the orbital muscle of Müller (projector oculi). The orbicularis palpebrarum, the frontalis, and the corrugator supercilii: the oculo-facial (superior division of the seventh).

These nerves arise superficially (fig. 22), as fol-

lows:—The third nerves: between the crura cerebri. The fourth nerves: outer side of the crura. The sixth and the seventh pair: the former between the pons and the anterior pyramids, the latter between the pons and the olivary bodies. The sympathetic: the first pair of thoracic roots.

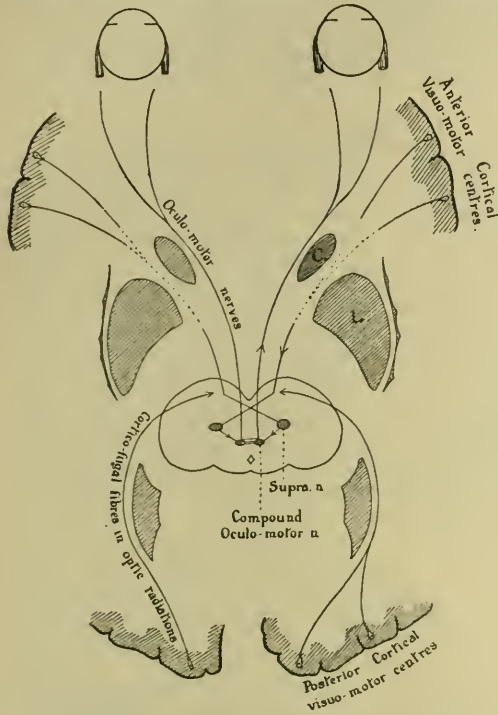

FIG. 21.—Horizontal section through the brain-stem (schematic), showing the visuo-motor tracts.

The third, fourth, and the sixth nerves course forwards and somewhat outwards to the sphenoidal fissure, and are for some distance embedded in dura. Of these the sixth pair run the longest

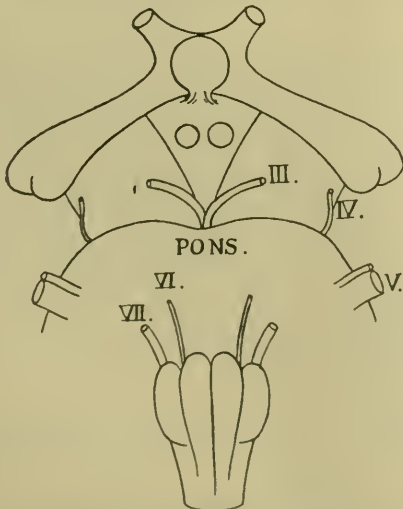

FIG. 22.—Diagram showing the origin of the visuo-motor nerves (as well as the fifth nerves) at the base of the brain.

course, and are, therefore, very liable to be involved in disease at the base of the brain, although as a clinical fact they are not so frequently affected as the third pair. The seventh nerve courses forwards and outwards to enter the internal auditory meatus.

b. The Nuclear Centres.—The nucleus of the sympathetic is situated in the cervical cord. The nuclei of the third, the fourth, and the sixth nerves form pairs on either side of the middle line. (Figs. 23-24-25-26.) Those of the third and the fourth are situated in the floor of the Sylvian Aqueduct,

FIG. 23.—Diagram showing the nuclei of the visuo-motor (and other) cranial nerves.

FIG. 24.—Diagram showing the origin of the third, fourth, and sixth nerves. A light-reflex neuron can be seen passing from the supr. corp. quad. to the third nerve. Notice the fourth nerve passing backwards to decussate with its fellow.

FIG. 25.—This diagram shows a light-reflex fibre traversing the optic tract, and terminating in the superior corpus quad., where it is placed in relation with a neuron, the axon of which passes directly into the third nerve.

extending along its entire length. The third nerve nuclei lie subadjacent to the superior colliculi and extend into the posterior part of the third ventricle. The fourth nerve nuclei, round in shape and much smaller in size, underlie the upper part of the inferior colliculi.

The cells of the anterior part of the third nerve

nucleus (in the walls of the third ventricle) are smaller than those of the posterior portion. The more mesially situated of these smaller cells are said to supply the ciliary muscle; the more laterally situated, the sphincter pupillæ. The main portion of the nucleus contains larger cells arranged in groups, each of which probably supplies chiefly, or entirely, a particular ocular muscle, but exactly what muscle, or muscles, each group controls is doubtful.

The axons of the third nerve nucleus (some of which decussate and issue with the third nerve of the opposite side) pass forwards and somewhat downwards in numerous bundles through the tegmentum and the red nucleus (Figs. 24-25) emerging from the brain-stem on the inner side of the corresponding crus cerebri (Fig. 22).

The axons of the fourth nerve nucleus—i.e., the fibres of the fourth nerve—have this peculiarity, that they all decussate. The nerve passes for a short distance towards the pons, and then turns sharply dorsalwards, and crosses over the upper part of the superior medullary velum just below the inferior colliculus (figs. 23-24), issuing from the base of the brain on the outer side of the crus (Fig. 22).

The sixth nerve nucleus lies in the floor of the fourth ventricle, at the lower part of the pons, just above the striæ acusticæ. It is immediately adjacent to the eminentia teres (some of the fibres arising from a small ventrally situated nucleus). The seventh nerve loops this nucleus in a peculiar way (figs. 23-24-26). The axons pass ventrally

FIG. 26.—Horizontal section through the inferior part of the pons, showing the principal and the accessory muscles of the sixth nerve, and the nucleus of the seventh nerve. The fibres of the sixth nerve on either side are seen passing forward.

and slightly caudalwards through the entire thickness of the pons, emerging from the brain-stem at the junction of the pons and the medulla.

Compound Oculo-motor Nucleus.—The nuclei of the third, the fourth, and the sixth pairs of nerves are all intimately connected by means of decussating, commissural, and longitudinal association (e.g., posterior longitudinal bundle) fibres, and thus may be regarded as forming a compound nucleus. This is represented in the accompanying diagram as an elongated parallelogram (Fig. 27). We may further suppose that part of each facial nucleus which supplies the protective muscles of the globes (i.e., the oculo-facial) has peculiarly close connections with this compound nucleus, since

there is a close functional association between these protective muscles and those of the globe proper, especially with the levator palpebræ, and we may therefore regard these portions of the facial nuclei as forming part of the "compound oculo-motor nucleus."

Not only are the individual nuclei of this compound nucleus closely connected one with another, but they are intimately associated (largely by means of the dorsal longitudinal bundle) with the remaining cranial nerve-nuclei. The connection with the vestibular nucleus is of special interest, in that it enables the ocular axes to be adjusted in accordance with alterations in the position of the head—e.g., when the eyes are kept fixed upon an object while the head is moved about in varying directions. This association further helps to explain the nystagmus resulting from lesions involving the vestibular nucleus, either directly or indirectly, as in cerebellar disease.

FIG. 27.—Diagram showing the situation of the oculo-motor nerve nuclei in the brain-stem. The nuclei of the third, the fourth, and the sixth nerves are arranged in pairs on either side of the middle line. All these are closely connected by commissural and association fibres, and form with the oculo-facial nuclei a compound nucleus, which may be termed the compound oculo-motor nucleus. By the action of higher supranuclear centres on this nucleus, the various conjugate movements of the eye are produced.

c. The Supra-nuclear Centres.—The compound oculo-motor nucleus is controlled by supra-nuclear centres which regulate the conjugate movements of the globes and of the lids. These are probably situated somewhere in the pons, or mid-brain (fig. 28). It is possible that some are located in the superior colliculi (superior corpora quadrigemina). These structures are the analogues of the optic lobes in birds and reptiles. In them they serve as the organs of visual perception, as well as for the visual reflexes involving the muscles (intrinsic and extrinsic) of the globes. In mammals the centres for visual perception are situated within the cerebral hemispheres, and the superior colliculi perform purely reflex functions. Their connections and functions in mammals are, however, by no means exactly known.

Retinal fibres, purely reflex (non-visual) in function, pass to the superficial layers of the superior colliculus. Fibres from the cerebral cortex reach the deeper "stratum opticum" through the optic radiations. On the other hand, no ascending fibres have been traced from the superior colliculus to the cortex. Fibres also reach this structure both from the mesial and the lateral fillet. Those from the latter subserve reflex movements of the eyes in response to auditory stimulation. From the deeper strata the tecto-spinal tract arises; the fibres of this tract swing round the central grey matter of the aqueduct, forming by their decussation between the two red nuclei the

fountain decussation of Meynart. They then course in the ventral portion of the posterior longitudinal bundle to the cervical portion of the cord, where they enter the ventral horns. Here they are brought into relation with the cervical sympathetic which sends fibres to the irido-dilator.

Fibres pass from the superior colliculus to the compound oculo-motor nucleus, and some directly into the third nerve.

d. The Cortico-fugal Supra-nuclear Fibres.—These fibres course from the visuo-motor centres in the anterior and posterior part of the cortex.

Those which come from the frontal cortex probably pass with the other cortico-fugal fibres pertaining to the motor cranial nerve nuclei, *i.e.*, in the geniculate tract (corona radiata, genu of internal capsule, and inner region of the crusta), although it must be admitted that no geniculate fibres have hitherto been traced into the oculo-motor nuclei. On this view they must travel as far as the pons before decussating, since the two crusta of the crura, unlike the tegmental portion which is united throughout, remain separate until they meet in the pons. Having reached the pons, the fibres would need to take a backward, and many of them, a recurrent course, in order to reach the neighbourhood of the oculo-motor nuclei, where the supra-nuclear centres are located. An alternate course would be through the undivided tegmentum. (The fibres from the frontal centre of the levator palpebrae are thought by some to pursue a different course.)

The visuo-motor fibres from the posterior cortical region course in the optic radiations towards the brain-stem. Their exact destination is not known. Some of them appear to pass (along with fibres from the auditory cortex) to the lateral part of the crusta. They are possibly connected with the supra-nuclear visuo-motor centres, or directly with the oculo-motor nerve-nuclei (and other cranial nerve-nuclei). It is possibly through these cortico-fugal fibres that the ocular movements resulting from stimulating the occipital region are produced.

From what has preceded it will be seen that the optic radiations contain *a* afferent visuo-sensory fibres, *b* fibres uniting the occipito-visual cortex of the two hemispheres through the splenium, *c* efferent fibres to the brain-stem. (Fig. 21.) Besides these fibres the radiations contain *d* the fibres of the inferior longitudinal fasciculus, which are thought to unite the occipital and temporal lobes. Of these various sets of fibres those from the corpus callosum (tapetum) are innermost; those of the inferior longitudinal fasciculus are outermost. These two sets are separated by the visuo-sensory fibres, which, however, are contained in all three layers.

e. The Cortical Visuo-motor Centres.—That all the visuo-motor nerves are represented in the cortex cerebri is manifest: in concentrated attention the pupils contract; in terror the pupils dilate, the upper lids are powerfully retracted, while the globes are thrust somewhat forwards (by contraction of the projectores oculi?): the lids can, moreover, be voluntarily opened and closed, and the globes rotated in a variety of directions.

The frontal visuo-motor centres (sensitivo-motor(a))—These are situated somewhat apart from the other motor centres of the Rolandic area, at the base, namely, of the second frontal convolution (Fig. 20.) From this region the eyes are converged, and moved from side to side, upwards and downwards. The protective muscles of the eyes, supplied by the oculo-facial, which is essentially a visuo-motor nerve, are said by some to have their cortical centre in the

lower part of the precentral gyrus (Fig. 20.) From this region the lids are raised and depressed.

Grasset terms these frontal visuo-motor centres *sensitivo-motor*, on the assumption that they may be reflexly excited by stimuli operating through the nerves of general sensibility, *e.g.*, the sensory nerves of the globe, as in the corneal reflex, and of the skin, as when the eyes are directed to a source of irritation (*e.g.*, a fly) on the nose.

The posterior visuo-motor centres (sensorio-motor).—It is probable that the frontal visuo-motor centres, like the neighbouring Rolandic "motor" centres, can be innervated from all the "sensory" regions of the cortex by means of association fibres. Thus in the sudden turning of the eyes in the direction of an object seen, heard or felt (as when *e.g.*, the shoulder is unexpectedly tapped), the frontal visuo-motor centres are enervated from the sensory areas pertaining to vision, hearing, and touch, respectively.

Special visuo-motor centres appear, however, to exist in the posterior part of the brain. Ferrier long ago showed that in monkeys visuo-motor effects follow upon stimulation of the angular gyrus; the

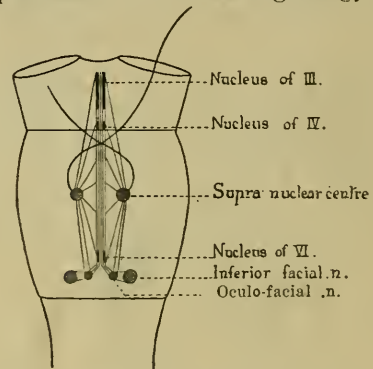

FIG 28.—The three pairs of ocular nerve nuclei III., IV., VI., and the pair of oculo-facial nuclei, all of which supply visual muscles, are represented as forming a compound nucleus. This is acted upon by supra-nuclear centres (of which one only is here represented), capable of so acting upon the compound nucleus as to give rise to the various conjugate movements of the globes and lids. The oculo-facial supplies the frontalis, corrugator supercillii, and orbicularis palpebrarum, all of which are visual muscles.

eyes are directed to the opposite side, and this movement is sometimes accompanied by contraction of the pupils and elevation of the opposite lid. A few clinical cases have been recorded of conjugate-deviation of the eyes and ptosis in connection with lesion of this gyrus. These facts suggest that special visuo-motor centres exist in the angular gyrus and its neighbourhood, and it is possible that the ocular movements produced by their stimulation are effected by efferent fibres passing direct to the brain-stem, and not indirectly through the pre-frontal centres. These motor effects are analogous to the pricking of the ears which may be obtained in some animals on stimulating the superior temporal convolution. Grasset assumes that these "sensorio-motor" visual centres can be directly stimulated from the retina (*i.e.*, from an organ of special sense), as when the eyes involuntarily follow an object. Similarly in so far as the retinal blink reflex is effected through the cortex it is probably through this sensorio-motor centre.

The position of the cortical centres governing the pupil and the ciliary muscle is not certainly known. There is some evidence that the pupil may be influenced through the angular gyrus and the occipital lobe.

(a) Grasset and other French writers employ the terms *sensitivo* and *sensorio* in relation to general sensibility (sight, hearing, etc.) respectively.

REFLEX STIMULATION OF THE VAGUS CENTRE IN THE TREATMENT OF DISEASE.

By A. T. BRAND, M.D., C.M.,

Physician, Driffield Hospital; Medical Officer, Driffield Workhouse Infirmary.

FROM time immemorial "counter-irritation" has been employed in the treatment of morbid conditions, by the application of the actual cautery, blisters, etc., to the skin overlying, or in the vicinity of, an inflamed or painful region, with the object of influencing the primary affection by the substitution of another and artificial inflammation; but no satisfactory explanation of the *rationale* of the method has yet been given. Dr. Cameron Gillies has written an exhaustive historical monograph on "Counter-Irritation," from which one gathers that this mode of treatment has no sound scientific basis. Inman says of "counter-irritants": "These substances act intensely upon the part to which they are applied; more gently, but yet severely, upon the parts below and around it; and more mildly, yet still decidedly, upon the whole system." This may be accepted as true, but it leaves the problem of the manner in which the alleged influence is brought about still unsolved. It is safe to say that the good result which follows is effected *via* the nervous system, and the term "contra-stimulus" of the Italian schools appears to suggest less vaguely the object the physician has in view; but the exact sequence of events still remains to be elucidated. I have been experimenting lately with this method of treatment in several diseases in which the ordinary text-book treatment has proved futile, with results so satisfactory that the following illustrative cases are recorded in the hope that others may also find benefit from its use on similar occasions.

EXOPHTHALMIC GOITRE.

Last year Kathleen M., *æt.* 27, unmarried, developed Graves' disease, in which the usual symptoms were present—*e.g.*, tremors, tachycardia, feeling of fulness in the throat, and exophthalmos, these two last being, however, slight in degree. There was no anæmia. The most distressing feature in the case was an intractable nausea, which all the usual remedies, including sinapisms over the epigastrium, were powerless to relieve in the smallest degree. So great was the gastric irritability that even sips of cold water were rejected, and the patient appeared to be rapidly sinking from inanition. Cocaine hydrochloride was given in half-grain doses in the hope of anæsthetising the peripheral distribution of the vagus, but only slight temporary relief was experienced. At last it occurred to me that if the vagus centre in the medulla could be reflexly influenced, a good result might possibly follow. To achieve this end, the skin directly over the course of the par vagum in the neck was irritated by applying linimentum iodi to an area of the size of a shilling, on both sides, immediately behind the angle of the lower jaw. As soon as blistering occurred, the nausea rapidly subsided, and disappeared in a few days, to reappear, though to a less extent, when the blistered parts had healed. Fresh blisters were induced just below the previous ones, when the nausea once more disappeared, and never returned. The patient was now able to take and retain food, and gradually put on flesh. Not only was the nausea entirely removed, but the heart was also beneficially influenced, the pulse-rate falling in a week or two from 120 to 140 per minute to 80, soon afterwards becoming normal. This favourable result was attributed to the afferent stimulation of the vagus centre causing efferent

impulses to be conveyed by the par vagum to the stomach and heart.

When the patient could retain food, etc., well, she was given "thyroidectin" (the inspissated blood of a thyroidectomised animal) in 10-grain doses, *t.d.s.*, which was continued for six months, and she is now practically well. How much of the recovery is to be credited to the thyroidectin it is impossible to say, but it is obvious that, unless the nausea had been checked, the patient could not possibly have taken any of it.

SPASMODIC ASTHMA.

Asthma is one of the most unsatisfactory diseases a physician is called upon to treat, and this is evidenced by the fact that the remedies suggested are legion. If, therefore, any means could be found to cope successfully with the malady it should be hailed as a boon, as much by the physician as by the patient.

For the last three years a very refractory case of this disease—Ruth H., *æt.* 50, married—has been under treatment, which the usual remedies, including a much-vaunted inhalation were unable to affect. Morphina alone had any control over the spasmodic attacks; but cure, not merely relief, was the goal aimed at, and, naturally, the routine use of this insidious drug is greatly to be deprecated. Encouraged by the success attending the reflex stimulation of the vagus centre in the previous case, where the gastro-cardiac distribution of the vagus was favourably influenced, it was deemed reasonable to expect that similar treatment would beneficially influence its distribution to the respiratory system. Blisters were accordingly induced on the skin immediately over the nerve in the neck on both sides as before. The expectation was not disappointed. The result was equally satisfactory, the asthma being decidedly relieved. The spasmodic attacks are now not only very much fewer, but much less severe when they do occur. The attacks used to last for several hours, but now, when one comes on and *lin. iodi* is painted on the neck over the par vagum until the skin smarts severely, the attack is cut short in half an hour.

PERTUSSIS.

In a case of whooping-cough, Muriel S., *æt.* 10, the paroxysms were exceeding frequent and violent, and the concomitant vomiting so severe that the patient was rapidly becoming emaciated and exhausted. Appetite was good, but food could not be retained long enough to be digested, far less assimilated. The outlook was gloomy in the extreme, and it was evident that, unless this condition could be relieved, recovery could not be looked for.

Again, the skin was blistered in exactly the same way over the par vagum, with the gratifying result that the paroxysms were at once not only greatly reduced in severity, but the interval between them was so much prolonged that the acts of vomiting became infrequent; food was retained and assimilated, and the child made a rapid recovery.

This treatment has been found to give great relief in affections of the respiratory system, especially where the cough is very frequent and distressing, with scanty expectoration. The frequency is greatly reduced, and the irritability markedly relieved.

NAUSEA AND VOMITING GENERALLY.

Not only in reflex nausea and vomiting does stimulation of the vagus centre, by blistering over the par vagum, exert a benign influence, but also in cases of pathological conditions of the stomach itself, and in my hands it has been found to act much more satisfactorily than sinapisms over the epigastrium, and the other usual remedies.

No opportunity has yet arisen to try this method of treatment in the vomiting of pregnancy, but analogy leads one to expect similar relief in this condition also. It has been found very satisfactory in "sick headache."

There is another form of sickness which is most distressing, as well as exceedingly common, which I have no opportunity of treating by reflex stimulation—viz., "sea-sickness."

It is reasonable to expect that this condition also would be favourably influenced, and I should be very glad if those medical men who "go down to the sea in ships" would take advantage of their ample opportunities to test this method of treatment on the victims of *mal de mer*.

If lin. iodi is objected to on the score of its staining effect, the liq. epispasticus or small circular cantharides blisters, etc., might be used, since all equally promote the object in view—blistering of the skin.

[Note.—Since writing the above the following communication appeared in the *British Medical Journal* of November 30th, 1912:—

"Lieut.-Col. C. W. Johnson (Brighton) writes:—Dr. Brand suggests trying vesication of the skin over the course of the vagi nerves for sea-sickness. Exactly twenty years ago I tried it on two officers of the I.M.S. on our way to India, who were prostrated and would not leave their berths. Within half an hour both felt well and were on deck and had no relapse. One of them tried it on his wife, with the same success. I put some chloroform on two bits of lint and put one on each side of the neck (between the mastoid and the angle of the jaw) and covered the lint with silk tissue. The patients kept it on until they could not bear the smarting any longer, I think about 10 or 15 minutes. Ladies with fair skins should be informed that a red mark is apt to be left on their necks for two or three days."]

The subject is a most interesting one, and the result of this treatment has been very gratifying, whatever the exact physiology may be. One cannot but conclude that the vagus centre and its neighbourhood are really influenced, directly or reflexly, by the cutaneous stimulation over the course of the nerve, which lies so near the surface in the neck, with the result that its peripheral distribution, cardio-pneumo-gastric, is powerfully affected, inducing a return to normal conditions of the organs innervated by it. Very severe irritation of the skin of the neck over the course of the nerve, applied to a large area, has been known to accelerate the normal heart-beat, the afferent impulses sent to the medulla causing a diminution in the tone of the cardio-inhibitory centre in the medulla, which normally regulates the cardiac rate. In the case of Graves' disease referred to, the tachycardia was pathological and the cutaneous irritation mild; and here the afferent impulses had the opposite effect—i.e., increasing instead of diminishing the tone of the medullary cardio-inhibitory vagus centre, thus augmenting its controlling influence on the heart and slowing its rate.

Nor is there anything incompatible in the same remedy causing slowing of the heart by increased activity of the inhibitory fibres of the par vagum, and relaxation of bronchial spasm by diminished activity of the motor fibres of the same nerve. Various sets of fibres in the vagus can act quite independently, and can be influenced quite differently by various conditions.

With regard to the gastric influence exerted by the vagus centre in the elimination of nausea, the exact method of its action is a matter for conjecture. The mechanism of the influence of reflex

stimulation upon the centres concerned in nausea and vomiting has not, to my knowledge, been experimentally elucidated. It may be that the afferent impulses sent up the par vagum to the medulla so influence these centres that their action is suspended or neutralised.

In the absence of definite knowledge, one must be content to have recourse empirically to this method of treatment of nausea and vomiting by reflex stimulation of the medulla, since it is successful in achieving the end in view.

I have been unable to find any reference in any text-book to such treatment of these morbid conditions, and venture to express the hope that it will be investigated by other physicians, believing that it will not be tried in vain.

CANE VERSUS BEET SUGAR.

By A. STAYT DUTTON, L.R.C.P.LOND.,

M.R.C.S.ENG.,

Oxford.

It is considered by some dental investigators that caries of the teeth is largely attributable to the use of sugar, and a high percentage of the decayed teeth in children has been said to be caused by eating sweets. Although it is, I think, difficult definitely to ascribe the occurrence of caries in any great proportion of cases to the local action of sugar in the mouth, in the same way that other carbohydrates are harmful, there are data which suggest that the usual food may be to a certain extent lacking in elements required by the teeth. The exact period when the disease began to become much more prevalent than formerly, as it is now generally recognised to be, has not, so far as I am aware, been decided upon. On interrogating persons of 70 to 80 years of age, it is notable they agree that the teeth of those a few years older than themselves and of their contemporaries as children and young adults, were far less affected than the teeth of their own children. Army statistics also show that the teeth of recruits have become decidedly more carious during the last 20 years, and although decay has been known from antiquity, it is likely a marked increase in its incidence, and which has since been progressive, took place between 20 and about 50 years ago.

In investigating the statistics in regard to the relative use of cane and beet sugar, it is found that in 1840, 4.35 per cent. of the world's sugar trade was in that obtained from beetroot; in the year 1870, 30.40 per cent.; and that in 1900 it had increased to 67.61 per cent., mainly owing to its augmented production in various European countries, of which the chief are Germany, Austria-Hungary, and Russia. With respect to the United Kingdom, in 1870, 556,000 tons of raw, with 3,000 tons of refined, cane sugar, and 84,000 tons of raw, with 82,000 tons of refined, beet sugar were imported; and in 1901 the amount was 178,472 tons of raw, with 1,000 tons of refined, cane sugar, and 526,451 tons of raw, with 1,079,553 tons of refined, beet sugar; thus showing that whereas in the year 1870, 559,000 out of 725,000 tons was cane sugar, in 1901 only 179,472 out of 1,785,476 tons was that derived from the sugar cane. In other words, while in 1870, 77 per cent. of the imported sugar was obtained from the latter source, in 1901 this had been reduced to 10 per cent. As to the yearly consumption per head, in 1875 the amount was 50.64 lbs. of raw, with 8.88 lbs. of refined, sugar; and in 1901, 36.80 lbs. of raw, with 56.40 lbs. of refined, sugar (a), thus indicating that while the average quantity ingested is greater by nearly

(a) "Encyclopædia Britannica," 1911.

34 lbs., the amount of refined sugar has increased sixfold. These figures show that since the year 1840, a marked alteration has taken place in the world's sugar trade, and in the habits of people in regard to the use of it. It is also noteworthy that the augmented importation and consumption of beet sugar in Great Britain, and in consequence the decrease, particularly since 1870, in that of cane sugar, has been contemporary with a decided increase in the occurrence of dental decay.

Notwithstanding that the chemical composition of cane and beet sugar is said to be identical, that there may yet be differences in it has not escaped the notice of observers, and Dr. Goulston stated in a paper read during the meeting of the British Medical Association at Liverpool last July, that he has elicited from three leaders in the chemical and physiological world that they maintain it was not inherently impossible for the former to contain a factor which is not present in the latter. (a) To one who holds that the predisposing and main cause of caries is due to the ineffective nutrition of the structure of the teeth, and that being constitutional in character it would necessarily occasion detrimental results in other tissues of the body, the question of the nutrimental value of foods and of whether any change in the use or preparation of them is operative in producing such, is of consequence from both points of view. Various matters concerning foodstuffs, among which are the preparation and refining of flour, the milling and polishing of rice, and the use of preservatives, have been recently considered in relation to their effect in the system, and it is possible that a re-investigation may reveal either that cane sugar possesses qualities which are not found in beet sugar, or that the methods now in vogue for the refining of sugar remove substances which are needed for the efficient nutrition of the body.

The amount of sugar that is consumed per head of the population is progressive, and owing to the greater mental and physical energy which is demanded as time goes on, seems likely to continue to be so; that sugar should contain its due nutritional qualities may thus become increasingly needful. The question also induces speculation of a different nature—namely, in regard to the advisability of continuing free trade in commerce—and while the opinions of those who are opposed to it may be correct as to the injury thereby occasioned to the material prosperity of the inhabitants of the country, there is, in addition, the possibility that their physical capacity is adversely affected by arrangements which, in leaving extensive areas in various parts of the Empire that are well suited to the growth of the tropical plant from which cane sugar is derived void of effective culture, have largely delivered the market into the hands of friendly, but foreign, Powers whose source of supply is that which is extractable from beetroot.

OPERATING THEATRES.

ST. BARTHOLOMEW'S HOSPITAL.

HÆMOPHILIA COMPLICATING APPENDICECTOMY.—MR. D'ARCY POWER operated on a boy, æt. 16, an only son born of Jewish parents, who had had a severe attack of appendicitis in South Africa in July, 1912. No details were available, but for some reason it had been thought inadvisable to operate, and the boy was confined to bed when abroad for a month. He came home and appeared to be in average health, except that he was anæmic and had a somewhat earthy complexion.

The operation was done at St. Bartholomew's on a Monday, the patient having been admitted on the pre-

vious Friday. The appendix was found to be retro-cæcal, short, and bound down by dense adhesions. It was removed without trouble, and with it a gland from the ileo-cæcal fossa. It was noticed at the time that the hæmorrhage was somewhat more free than usual, and that it did not come from any definite vessel. The operation was performed at 3.30. About two hours afterwards it was noticed that the pulse was failing. The local condition was therefore examined; no dulness was found in the flanks and there was no external bleeding. Tinct. opii 20 m. was administered. His condition did not improve, and at nine o'clock Mr. Power found him pulseless, sweating profusely, and with dilated pupils, restless and quite conscious. Mr. Power had no hesitation in saying that the patient was suffering from concealed hæmorrhage. The boy was at once taken to the theatre and the wound re-opened. A large quantity of fluid blood was washed out of the pelvic cavity. The retro-cæcal area was carefully examined, but no bleeding point could be discovered, and it was therefore packed systematically with sterilised gauze. The patient was very collapsed on returning to the ward, but his condition was improved by intravenous injections of simple saline solution at 120°. He rallied fairly well by the next day, when the plugging was removed; it was stained with fluid blood, but there was no free escape. On Wednesday morning the boy began to vomit and had hiccough, the abdomen became distended, so that Mr. Power thought he had peritonitis, but his temperature never rose, and his pulse was from 130 to 140. The vomiting was relieved by washing out the stomach, but this relief proved to be only temporary. On Thursday, as his condition had not improved, although he had passed a little flatus, Mr. Power re-opened the abdomen. However, he found no evidence of peritonitis, but that a considerable quantity of fluid blood had again accumulated in the retro-cæcal region. The appendix region was free from any plastic deposit, and the oozing had been quite general and not from any definite bleeding point.

The boy died on the same evening, in spite of every attempt to maintain his blood pressure. No *post-mortem* could be obtained.

Mr. Power said that the occurrence of severe bleeding after an appendix operation was a very unusual thing to happen; it might take place superficially to the peritoneum from the deep epigastric artery or vein when the longitudinal incision had been made through the rectus (called Battle's incision), or it might occur from an imperfectly secured meso-appendix artery. In the present case, however, it had not emanated from any vessel, but there was a general oozing from the whole of the retro-cæcal area, the blood showing no tendency to coagulate, although the boy lived four days after the first operation. The case must therefore be classed as a type of hæmophilic bleeding, and to this the Jewish ancestry of the boy would give some support, as it is known that this disease is somewhat more often recognised in the Semitic races, perhaps, he thought, on account of their early circumcision, when the affection is discovered. The condition is fortunately rare, he pointed out, but must of necessity be the most serious complication occurring in the course of an operation of appendicectomy, which is usually looked upon without much fear. Under the present state of our knowledge this complication must necessarily prove fatal.

The Royal Surgical Aid Society.

At a luncheon recently held at the Cannon Street Hotel to celebrate the jubilee of the Royal Surgical Aid Society, Lord Aberdeen (President of the Society) presiding, it was stated that the Society, which was established at a little shop at Ludgate Hill in 1862, is now the largest to supply all kinds of surgical appliances to the poor, irrespective of creed, and the Committee is appealing for donations to a jubilee celebration fund. During its existence the Society has supplied 750,000 appliances. The first year's income was £240—this year it was £27,469.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

MEETING HELD WEDNESDAY, DECEMBER 4TH, 1912.

The President, SIR ANDERSON CRITCHETT, C.V.O.,
in the Chair.

THE subject for discussion was

THE PHYSIOLOGY OF THE INTRAOCULAR PRESSURE.

Dr. LEONARD HILL, F.R.S., in opening the debate, said the reason Dr. Black and he appeared before the Society was because some researches which they had been carrying out on the relation of the general circulation to secretion led them to investigate the eye. The subject had already been brought before the Royal Society, but there were some new points which he would speak on. For the purpose of measuring the intraocular pressure, Mr. Thomson Henderson and he made some experiments because with the ordinary hypodermic needle they could not avoid leakage in the track of the needle. The result was, they devised a needle which did not permit of leakage. They found, by very carefully checked experiments, that the aqueous pressure varied within fairly wide limits, depending on the blood pressure: the higher the arterial pressure, the higher was the aqueous pressure. In one case, under chloroform, it was 16 m.m. of mercury, and under ether narcosis, when the animal was in good condition, going up as high as 62 m.m. By a compensation method they obtained readings which seemed to agree, so there seemed but little chance of error. It was very important that the pressure of the aqueous should be positive, because that kept the eye-ball as a perfect optical instrument. Its distension, in their opinion, was maintained by secretory pressure. Though the pressure varied anywhere between 10 and 50 m.m., according to the condition of the circulation, the eyeball retained its shape. The pressure in the capillaries and the pressure of the aqueous must always be the same. In a previous investigation they found that the pressure of the cerebro-spinal fluid and the pressure of the blood in the cerebral veins was the same, and the two varied together. Various workers had made investigations, and it was found by viewing the retinal vessels with the ophthalmoscope that the flow ceased in them when the pressure reached that of the general arterial blood. Dr. Hill and his colleague punctured the cornea of a cat, and then on gently pressing the abdomen the iris on the same side immediately burst into hæmorrhage. All the capillaries allowed the blood to escape, and that came off every time. The explanation was that the normal aqueous pressure was exactly counterbalancing the capillary pressure. The aqueous had a definite chemical nature, and its osmotic pressure was said to be higher than that of the serum. Ehrlich demonstrated, by the injection of fluorescence, that some kind of circulation was proceeding in the aqueous. It seemed, from careful inquiry, that the cribriform ligament was opened up, and thus a passage was made for the fluid into the supra-choroidal space. That transference of fluid would allow accommodation to take place. The suspensory ligament was always taut, exerting elastic traction on the lens and causing it to assume its proper shape. The intraocular tension was said to be due to the elasticity of the lens, but it had no elasticity, for when removed it was a soft, pudding-like body. In the act of accommodation the muscle contracted, but continued to be of the same volume as the uncontracted muscle; on contraction it really moved inwards, as described by Thomson Henderson, and allowed the fluid to pass from in front of the lens either into the spaces of the ciliary body, or into the space of the cribriform ligament and into the supra-choroidal space.

Professor STARLING, F.R.S., said most would agree with the facts which Dr. Leonard Hill had advanced, but he was not in close agreement with some of the interpretations which the opener placed upon them.

It was important to have some idea of the factors determining the formation and absorption of the intraocular fluid, but more important to know what those factors were. It seemed to be generally agreed that the seat of production of the intraocular fluid was the ciliary processes, and the chief absorption was at the anterior angle of the eye, and some probably occurred at the root of the iris. Covering the ciliary processes was a well-marked epithelium, containing columnar or cubical cells, which might well be endowed with the property of secretion, as they were as well formed as those of the salivary gland, or of the kidney tubules. What were the conditions which must be observed if the intraocular fluid was to be regarded as a filtration? The intraocular fluid was at considerable pressure, so there must be resistance against its flow from the eyeball. But if the pressure there was in consequence of the pressure of the blood in the vessels, the pressure of the intraocular fluid must go up with the rise of pressure in the vessels. When the carotid or subclavian artery was obstructed, cutting off the blood supply from the eyeball, the pressure came down; and it went up again in proportion to the amount of blood one allowed to enter those vessels. One could take 25 m.m. as the average intraocular pressure. Stimulation of the sympathetic nerve caused a double effect—first, contraction of the unstriated muscle fibres of the orbit and a rise of pressure, and as the vessels of the ciliary process contracted so as to diminish the blood pressure in these vessels, there was a fall also in the intraocular pressure. There was a quick rise due to contraction of the nictitating membrane and the unstriated muscle fibres, and a rise of pressure. As the formation of intraocular fluid passed off, there was a fall of pressure, accompanied by constriction of the vessels of the eyeball. He contended that the blood pressure must be higher in the vessels all the way along than outside and than the intraocular pressure, and the quicker the rate of flow through the system of vessels concerned the greater must that difference of pressure be. There was no reason for saying it was impossible for a difference of pressure to exist between the capillaries and the fluid outside, but there was every reason for assuming there must be a difference. One could not know how much fluid came out until one ascertained what was the rate of transudation. If the pressure remained constant, that rate was the rate of absorption. Professor Starling showed a number of slides to illustrate his point. It was impossible to measure the pressure in the capillaries under normal conditions. By increasing the pressure of the intraocular fluid one brought up the pressure in the capillaries towards that in the arteries. At some future time it might conceivably be shown that the cells coming from the ciliary processes might act as regulators, but at present there was no evidence that they acted otherwise than as guiding and strengthening the filtering membrane. In regard to the relationship of the capillary to the venous pressure, he had never been able to understand Dr. Leonard Hill's position on that point. Into the mechanism of accommodation he did not propose now to enter, except to say he supposed it to be due to a shifting of fluid between the posterior chamber and the anterior chamber, which could easily take place, as there was no resistance between the fibres and the suspensory ligament.

Mr. PRIESTLEY SMITH (Birmingham) said it was important to know what was the normal pressure in the human eye. It certainly varied in different people and in the same person at different times; but what would be a fair average? A pressure of 60 m.m. which had been mentioned would surely mean that the person had glaucoma. Dr. Hill had said that the intraocular pressure was equal to the venous pressure, and to the pressure in the capillaries. He (Mr. Smith) thought it was equal to the venous pressure at one point—*i.e.*, where the blood left the eye, but that at every other point the intraocular pressure was lower than the blood pressure. Dr. Hill had not shown that the pressure in the torcular herophili was equal to the pressure in the veins and the other parts of the skull; and, as Professor Starling said, there could not be equality of pressure or there would be no movement.

But the difference in pressure was probably only very slight. He did not see how Dr. Hill could hold it as proved that the pressure in the capillaries of the ciliary body was the same as the pressure of the intra-ocular fluid; and every probability seemed to be against that view. It was generally acknowledged that the intra-ocular pressure was produced by the ciliary processes, and he believed the ciliary body also played a part. There was no question that the vitreous fluid was removed, but did it come from the posterior surface of the process, or from the *pars plane*? He expressed his objection to the use by some, even chemists, of the term "tension" instead of "pressure." There had been a controversy as to whether the tension of the eye depended on increased volume or to increased pressure of the blood. Such a discussion was futile, because it depended on both.

The discussion was postponed until the next meeting of the section.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, NOVEMBER 29TH, 1912.

MR. A. BLAYNEY in the Chair.

RADICAL OPERATION FOR MALIGNANT DISEASE OF THE TESTICLE.

MR. SETON PRINGLE read a paper on "Radical Operation for Malignant Disease of the Testis." After dealing with the pathology of new growths in the testicle, he described the lymphatic drainage of the organ and the general anatomy of the region of the operation, illustrating his remarks with lantern slides. He laid stress on the fact that good results could be hoped for only if the operation were undertaken early, before the involvement of the secondary glands. The case which he reported was one of cancer in the left testis of a man aged twenty-eight. The operation was done by the extra-peritoneal route, and in this way the testis, cord, inguinal glands, spermatic vessels right up to the renal vessels, the psoas fascia, lymphatic channels and lumbar glands were all removed in one piece, as was well seen in the specimen which he exhibited. The patient made good progress, and now—six months after the operation—showed no sign of recurrence. The pathological report stated that the growth was a "mixed tumour" of a carcinomatous type, and that although the glands were enlarged, yet they showed no sign of malignant infiltration.

The CHAIRMAN congratulated Mr. Pringle on the paper. He said that in the present state of knowledge the only effective treatment in such cases was radical operation.

MR. GUNN said he had an opportunity of seeing the operation carried out by Mr. Pringle, and it appealed to him as an excellent method of trying to relieve the severe form of disease. He alluded to the danger of recurrence, and said that in three cases in which he had removed the testes for sarcoma he was afraid recurrence had taken place. He considered that there was a difficulty to be faced in making a diagnosis of the nature of the tumour, as to whether it was a simple cystic dermoid or a very malignant form of sarcoma—the latter he was afraid was hopeless. During the operation there was an excellent view of the structures to be dealt with. He inquired if since the operation was performed there had been much alteration of the abdominal wall.

MR. PRINGLE, in replying to the remarks, said in speaking of dividing up tumours into two classes—sarcomatous and carcinomatous—for purposes of operation he did not include amongst the sarcomatous mixed tumours in which there were a few sarcoma cells. The abdominal wall since the operation is perfect, and there was no sign of hernia or any trouble of the kind. He pointed out that so far as diagnosis was concerned he advocated the taking out of a small piece for microscopic examination.

A YEAR'S EXPERIENCE OF DIORADIN IN SURGICAL TUBERCULOSIS.

MR. R. ATKINSON STONEY read a paper in which he gave the results of twenty-eight cases of surgical tuberculosis treated by injections of dioradin. He had reported on fourteen of these a year ago, since which nine had received a second course of injections. He divided the cases into two classes, according as to whether they were complicated by sepsis or not. There were fifteen non-septic cases, and of these seven resulted in apparent cure, four were greatly improved and would probably end in cure, two were somewhat improved, one was not improved, and one which improved greatly for a time died later of tubercular meningitis. In the septic cases there were four apparent cures, two were greatly improved, and will probably result finally in cure, one was somewhat improved, and five were not improved, and one which improved died later of acute nephritis. Altogether, there were six cases without apparent improvement. One of these was an advanced septic hip, where it was very doubtful if there had ever been any tubercular trouble, another was advanced cystitis with probable double nephritis; three were cases of very extensive multiple lesions, and one was an early case of epididymitis. The first five of them were all practically hopeless cases, and could not be expected to respond to any treatment, but the case of epididymitis was a distinct failure, as it was discovered early, but progressed steadily and rapidly in spite of injections, and the disease was found at operation to be actively spreading. Having given over 3,000 injections, he could say that he had never seen them do any harm or give rise to any discomfort even if given subcutaneously instead of intramuscularly. The following were the conclusions that might be fairly drawn from these cases:—(1) Dioradin injections are not a certain cure for all cases of tuberculosis; in some cases they will produce a cure more rapidly and more certainly than any other treatment. (2) Early cases of joint disease treated by injections, combined with ordinary methods of rest, good food, etc., will recover more rapidly and more surely than when treated without the injections. The same is probably true of glandular and other surgical affections. (3) In advanced cases with abscess formation, if injections are started before or at the time the abscess is opened, it will usually heal rapidly, and the tubercular process apparently come to an end, and a cure result in a large proportion of cases. (4) Finally, in those cases complicated by septic infection, dioradin injections will certainly reduce the temperature to normal, increase the appetite and weight, and lessen the amount of discharge, and in some cases even bring about a final cure, as in three of the cases reported in the paper.

The CHAIRMAN congratulated Mr. Stoney on his impartial and judicial survey of the symptoms presented by the cases, and considered that in the summing up he (Mr. Stoney) had not claimed too much for the method. Dioradin appeared to render considerable assistance in dealing with the disease. There was one objection, however, to its use—*i.e.*, the expense. He thought very few hospitals could afford it.

DR. KIRKPATRICK said that he had but small experience of the method, and that the patients with whom he had tried it were not suffering from surgical tuberculosis, but from phthisis. He was sorry to say that he did not see any improvement which could be attributed to the treatment. Four of the five cases which he had under observation last year came to a fatal termination; the other was a man of advanced age who had an involved tubercular lesion at the base of the right lung, and he improved considerably, and left the hospital expressing himself as quite well, although he (Dr. Kirkpatrick) could not satisfy himself that he was perfectly well. Some of his cases had been seen and examined by Dr. Bernheim, who considered them suitable for dioradin treatment. He had seen a number of other patients who had been treated with the drug and subsequently with injections of iodoform suspended in ether, and it appeared to him that they reacted quite as favourably

with the latter as when treated with the radio active substance. He considered that the radium in dioradin was added to it in order to influence the imagination of the patient. It appeared to him that the active substance in the drug was iodoform, and injection of iodoform in certain cases had been followed by good results. He suggested that it would be of interest to proceed with the investigations and try what the results would be from using an ethereal suspension of iodoform in a similar set of patients.

Mr. C. A. BALL inquired if there was only one out-patient treated in the series. This he considered a very important matter, as when surgical cases are taken into hospital a very large proportion of them put on weight.

Mr. GUNN said that he had six cases of tubercular disease under treatment with injections—two of them with dioradin and four with a preparation supplied in Dublin which was much the same. Of the six cases one had done extremely well, and it was treated with the inexpensive drug, one was too recently treated to draw any conclusion, and the remaining four had shown no improvement. All these cases had been treated with tuberculin before this without result, and he would like to know if the tuberculin treatment had any influence on the dioradin treatment. The proportion of failures in connection with the treatment of cases of tuberculosis of the ankle and foot, as compared with any other part, was remarkable. He considered any form of treatment which would have a good effect on cases of lupus was important, as in such cases it could be seen what was actually happening.

Mr. STONEY, in reply, said he had only treated five cases of phthisis with dioradin, and the results were not very satisfactory or definite. One remarkable case in which there were complications was given injections of dioradin, and the patient increased nearly a stone in weight, the sputum was reduced, and the cough relieved. He was not, however, sure how much of the improvement was due to the relief of the complications and how much to the improvement in the lungs. There was only one out-patient treated, and in that case injections were only given every second day. Many of the patients had previously been in hospital for periods from three to fourteen months without improvement.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, DECEMBER 4TH, 1912.

The President, Mr. J. M. COTTERILL, in the Chair.

DR. BYROM BRAMWELL opened a

DISCUSSION ON MALINGERING.

He defined a malingerer as one who feigned sickness or injury or who knowingly and wilfully exaggerated symptoms of illness or injury in order to obtain sympathy or for monetary interest. There could be no such thing as unconscious malingering. Until recently malingering was not so common and was usually seen in the case of soldiers, sailors, prisoners and schoolboys, and was also met with in cases of railway accident. Since the passing of the Workmen's Compensation Act and the Employers' Liability Act, malingering had been much more common. In his book on the spinal cord, Dr. Bramwell had stated that colliers who had suffered from concussion of the spine very rarely suffered from organic disease of the cord or membranes and rarely from the kind of symptoms seen after railway accidents. He had predicted that after the passing of the Compensation Act symptoms following accidents due to falls of coal or stone would be much more frequent. This prediction had been abundantly verified. He now ventured to predict that under the National Insurance Act both malingering and valetudinarianism would become much more common than they were now.

There were several varieties of malingering.

1. Healthy persons might feign or induce disease and claim compensation. This variety was very rare. It was practically limited to club patients, schoolboys and

a few hospital birds. It was seen after railway accidents. He recalled the case of an old gentleman who was seated in a train which ran into the buffers. He was thrown gently into the arms of a very buxom lady and his hat was indented—the only injury. However, symptoms developed and got worse and the railway company paid £100.

2. There were cases where after accident or injury the symptoms of previous disease were attributed to the accident. These were more common and much more difficult to deal with. Dr. Bramwell had known cases of congenital club-foot, old facial paralysis, ear discharge, corneal scars, gonorrhœal conjunctivitis, epilepsy, tabes and spastic paraplegia to come into this group. In most cases the patient was aware of the previous condition, but he might not know. The medical man must carefully record the history and ask himself whether the accident was sufficient to account for the symptoms. There was great room for difference of opinion, and this class of case raised the whole question of the relation of trauma to disease. If a man was diseased before he was injured he was not debarred from compensation, but he should not obtain compensation on the same scale as a healthy person.

3. There was the class of case where patients suffering from the effects of accident or injury, or from illness not due to accident or injury, did not recover so rapidly as they might reasonably be expected to do.

In such cases it might pay the patient to be ill or remain ill. In many cases there was no inducement to get well. No effort was made and the symptoms persisted. These were cases of valetudinarianism. The patient had no intention to deceive, but the stimulus of hope was wanting. The chief factor in getting such patients well was to get litigation settled.

Cases of valetudinarianism were of the greatest difficulty and the greatest importance. A special difficulty was where to draw the line between valetudinarianism and partial malingering. In ordinary cases of dyspnoea—bronchial, cardiac or neurasthenic, could the physician say definitely when a patient might safely resume work? In ordinary circumstances family exigencies might lead a man to resume work too soon, but many such cases became valetudinarians.

The diagnosis of valetudinarianism and malingering must be based on careful medical examination and collateral non-medical evidence. Dr. Bramwell said he could simulate epilepsy, angina pectoris or insanity and defy detection, but the malingerer usually overacted his part. There was often, however, sufficient difficulty in distinguishing between organic and functional disease even in non-compensation cases, and great room for difference of opinion. Paralysis of the external rectus, reaction of degeneration, Babinski's sign, ankle clonus, paralysis of sphincters, optic neuritis and changes in the cerebro-spinal fluid were all signs of organic disease, but there were exceptions. Electrical tests were not often very helpful. When a contracted joint relaxed under chloroform that was not necessarily evidence of malingering, but modern methods such as X-ray examination, the perimeter, etc. might give much help.

The collateral non-medical evidence included the existence of unusual symptoms, traps, etc. It was a serious responsibility to certify a patient as a malingerer, and the doctor who certified should be independent of the result.

The procedure advisable in order to detect and prevent malingering under the National Insurance Act would be (a) careful examination by the ordinary medical attendant; (b) in doubtful cases examination and report by a specialist not on the panel and independent of the result; (c) if necessary, prolonged observation in hospital; (d) a time limit for money compensation on cases of neurasthenia and other conditions in which there was no evidence of organic disease.

Dr. GEORGE MACKAY said that the eye was so sensitive an organ that it protected itself from irritation by the malingerer. Before the Compensation Act cases were mainly blinking eye-lids in children or soldiers. Now cases of alleged partial or complete blindness

were common. When a patient alleged he could not see and the pupil showed reaction, blindness could not have arisen from direct eye injury. The examiner could then start off with the assurance that the patient was a liar, and quite good sport could be got with a malingerer. There were numerous tests by which binocular vision could be detected. A prism might be placed in front of an alleged blind eye, and the inexperienced malingerer saw two images. Complementary colours and strong curved lenses might be used. There were many cases on the borderland of malingering and hysterical suppression of vision.

Sir THOMAS CLOUSTON said that malingering was a normal fact in nature. It was found among the insects and reached a high level among birds in the endeavour to protect themselves or their young. Malingering and valetudinarianism was seen most in neurotic subjects. Melancholia often exaggerated symptoms. They wished to appear more insane than they really were. By nervous suggestion a patient might produce real nervous disease.

Sir GEORGE BEATSON said that many of the cases of malingering were due to the activities of our legal brethren. He reminded the Society of the old story concerning an injured person who replied to the query whether he was much hurt, "I don't know; I haven't seen my lawyer yet." There should be more stringent rules about the kind of cases allowed to come before the courts.

Dr. J. M. BOWIE said that in many cases the lawyer prevented a client from going back to work till his claim had been settled. He said that under the National Insurance Act malingering would entail enormous expense to the State, to employers and beneficiaries. If the beneficiary had to contribute towards the cost of medical advice much valetudinarianism would be checked at the outset.

Mr. CATHCART said that he always made a point of allowing the patient to tell his own story. He had found the condition of muscular development an important help in connection with injuries to joints and limbs. There could not be prolonged loss of power without some atrophy. If a patient's attention was distracted he often performed actions which he alleged were impossible.

Dr. EDWIN BRAMWELL insisted on the distinction between malingering and functional disease. They might, however, be combined, and even combined with organic disease.

Dr. J. V. PATERSON said he had had a very large number of compensation cases in connection with the eye. Gross malingerers were rare. The common type was the patient who exaggerated symptoms. The ophthalmic surgeon could, however, comparatively easily make up his mind regarding the facts. He protested against the same type of case being brought repeatedly into the courts.

Dr. SYM remarked on the differences in the value of an eye to different classes of workers and on the difficulty an injured man might have in finding fresh work. One little bit of good might result from the Insurance Act—viz., the recording of the condition of given persons on given dates. Stringent measures should be adopted against the malingerer for gain. It was as much theft to defraud an employer in this way as to pick his pocket.

Dr. CHALMERS WATSON put forward a plea for co-operation between the patients' medical adviser and the insurance company's medical officer. Permanent damage was sometimes the result of imperfect treatment.

Dr. DICKSON said that in colliery practice there was not so much malingering as valetudinarianism. He regretted to find that the *morale* of the Fife miner had been sadly undermined by the Compensation Act. Before the introduction of that Act the average duration off work after a simple fracture below the knee had been three months. Since the Act the average duration had been over six months. He thought the time would increase four-fold under the National Insurance Act. It was no use to try to distinguish neurotic patients. They were all nervous as soon as

they were hurt. In the mining villages neurasthenia was discussed at the street corners and traumatic neurasthenia was a common topic of conversation at the pit-head. The opinion of fellow-workman had no deterrent effect on the malingerer or valetudinarian.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Dec. 7th, 1912.

CANCER OF THE ŒSOPHAGUS.

PROF. LIEBMEISTER has recently shown by radiography and examination of anatomical specimens that absolute stenosis does not exist in cancer of the œsophagus and of the cardia. No matter to what degree the stenosis exists there remains always a small canal to allow liquids to pass. Real and absolute stenosis occurs only when the canal is blocked by food insufficiently divided or the products of the tumour in a necrotic condition. In these cases M. Liebmeyer gives a solution of oxygen water of from 1 to 3 per cent. by tablespoonfuls every hour.

In less than 24 hours the stenosis disappears, and at the end of a few days the patient, who previously could swallow nothing, can take food more or less liquid, and even solids. Several patients thus treated finished not only by eating quite easily, but even took on flesh and returned to an appearance of health. In a case of carcinoma of the cardia the weight increased by 16 lbs., and in another of enormous carcinoma of the stomach the gain was 8 lbs.

A patient was brought to the hospital presenting absolute stenosis of the œsophagus. A few hours after admission, and under the treatment of oxygen water, he was able to take liquids, and two days after thick soup passed, and a week later he could take solid food. In a month he gained 12 lbs. and left the hospital, but continued to use the solution. After a time he left it off for several weeks, when the difficulties returned. He re-entered the hospital, when he was simply put on the same treatment, and a fortnight after he had gained 14 lbs. At the end of some weeks he was admitted to the hospital for the third time, but now he was much wasted; nevertheless, after recommencing the treatment he gained 4 lbs. It is needless to say that all the cases terminated fatally, but life was considerably prolonged and suffering much relieved, facts of no small importance. The method has the advantage of being simple and presents no danger or inconvenience, and is capable of rendering great service in inoperable cancer.

CACODYLATE OF SODA.

The administration of cacodylate of soda by the mouth or by the rectum is frequently accompanied by divers accidents. Gautier attributes these accidents to the reduction of cacodylic acid in the digestive tract and the setting free of oxide of cacodyle. This last, of a strong garlic odour and very poisonous, determines frequently, even in small doses, a garlic odour of the breath, the faces and sweat, noticed particularly by those who approach the patient. Other authors have reported symptoms of intolerance, such as cramps in the stomach, dryness of the mouth, loss of strength and appetite, etc. For these reasons, Levrat of Lyon, says the *Monde Médical*, sought to render more practicable the administration, by the hypodermic method, of cacodylate of soda. M. Levrat treated over 1,000 patients suffering from pulmonary tuberculosis during ten years by injections of cacodylate of soda in progressively increasing doses, arriving thus at injecting much stronger doses than usually recommended. In every appropriate case where the caverns were not infected and the extension of the malady not too rapid, he found that the appetite was much increased as well as the weight of the subject, while there was a manifest and general improvement in the strength of the patients. His formula is:—

Hydrchl. of cocaine, 0.05.
Hydrchl. of morphia, 0.10.
Cacodylate of soda, 15 grm.
Sol. phenic acid (5 per cent.), 4 drops.
Water, 100 grm.

This solution can keep for a long time and is completely painless. Each syringe contains 3 gr. of cacodylate, and 6 gr. may be given (adult) at the one time and repeated three times a week, but the dose may be double—that is to say, 12 gr., according to the tolerance of the subject. Dr. Patry gives the full dose (12 gr.) three times a week, and never had any accident. In certain patients the injection has been followed by a slight rise in the temperature, but, as a general rule, fever is a counter-indication to the administration of cacodylate of soda. In these cases methylarsenate of soda or arrhenal should replace the cacodylate. It was asserted that cacodylate provoked albumin, but neither Levrat nor Patry ever observed it.

The results of this method were excellent. Descombiens asserts having assisted at almost miraculous cures by the rapidity with which they were produced in cases of tuberculous glands. A patient had very voluminous glands in the neck; so large were they that the uninitiated took them for goitre. After ten injections of 6 gr. each they all disappeared as by enchantment. In tuberculous patients who present an affection of latent character with bronchitis more or less generalised, this treatment works wonders. The râles disappear, the secretion dries up as if a kindly breeze had swept the mucous membrane; and the appetite returns; the dyspnoea ceases. Hæmoptysis is not a counter-indication, the cacodylate rather helps the patient to repair his loss.

Dr. Patry uses a formula which differs from that of Levrat; he leaves out the cocaine and the morphia, and doubles the dose of cacodylate:—

Cacodylate of soda, 30 grm.
Sol. phenic acid (5 per cent.), 4 drops.
Distilled water, 100 grm.

Each syringe (pravaz) contains 6 gr. of cacodylate.

GERMANY.

Berlin, Dec. 7th, 1912.

At the Verein für Innere Medizin und Kinderheilkunde, Hr. Kraus gave an address on

CORRELATIVE DISTURBANCES OF DEVELOPMENT AND GROWTH IN THEIR RELATIONS TO TUBERCULOSIS.

The question was what anomalies of the body as a whole showed a special tendency to tuberculosis? Also whether there were certain groups of tubercle which might be stigmatised as constitutional? First there were the relations between lymphatism and tuberculosis. Both pathological anatomy and the records of life insurance companies had already afforded material towards deciding that question. There was still, however, a good deal to be done on the subject, and especially in regard to family disposition. Passing over the scrofulo-tuberculosis of childhood to the lymphatism of the adult, residua of youthful lymphatism were often met with as far as the end of the fourth decade of life. Although it was easy to diagnose lymphatism in the mortuary, it presented great difficulties to the clinician. A great advance had been made here, however, by means of the use of X-rays. Lymphatism and the habitus asthenicus were frequently mixed up with each other. No doubt the lymphatic formed a special group amongst the tuberculous cases. Moreover, where there was absence of external swelling of glands, Röntgen examination of the chest revealed swelling of the glands of the hilus, and more or less numerous adhesions of pleura. The tuberculin reaction of these cases was generally positive. In such cases the tuberculosis was rarely progressive. But in later years tubercle was frequently found—of the eye; the urogenital apparatus, or the suprarenal capsule. Most probably a juvenile pulmonary tuberculosis lay at the bottom of these cases, which had attacked the glands of the hilus secondarily. A second form of tuberculosis was often met with at the end of the first or second decennium, which, on the contrary, proceeded from the glands of the hilus and

passed thence to the lungs. In these individuals all the tuberculin reactions were positive. In the third group the tubercle was not localised, but generalised in the whole of the lymphatic apparatus. They were the forms of the nodular, tumour-like tuberculous lymphomatosis. The glands had no tendency to break down. Microscopically one found numerous tubercles, here and there granulomatous tissue. The tuberculin reaction was always positive. A comparative amount of lymphocytosis or polynucleosis was found in the blood. The fourth group was that of generalised lymphogranulomatosis, the form described by Sternberg, and which, according to him, should be a form of tuberculosis.

Histological tuberculous changes were not met with in these forms of disease. But in spite of this the disease was most probably of tuberculous origin. The cases had increased in numbers the last few years, in which in part, through experiment on animals, tuberculosis was demonstrated, and, in part, in anti-formin sediments, the granular virus of Much. These cases did not give tuberculin reaction, but a weak Wassermann one, and in one case in the second medical klinik the complement combination with tuberculin was positive.

Passing to the habitus asthenicus, he pointed out that the phthisical thorax was by no means a long one, but that the lumbar spine was of abnormal length. Lenhoff's index had done him good service in taking the measurements. Everything pointed to the fact that the habitus phthisicus was present before the tuberculosis. The "tropfen" heart was a part symptom of the habitus asthenicus, but whether it had any relation to tuberculosis had not been cleared up.

AUSTRIA.

Vienna, Dec. 7th, 1912.

CANCER.

At the Gesellschaft der Aerzte, Kraus criticised Freund's results which he recorded at a former meeting with reference to the cell reaction in carcinoma. His own research in this direction was that very few gave the same reaction where cancer was not far advanced, and in epithelium carcinoma it was absent. He agreed, however, with Graff that the gravid female in the tenth month had an analogous cell reaction to the serum of the carcinomatous patient. In following this argument we have to accept the Ishiwara and Winternitz results that the embryonic cell was analogous to the carcinomatous cell as the relation of the blood serum in the gravid is in direct connection with the advanced foetus. Whether this exchange of the serum between the mother and child is the direct cause of this cell property has not yet been proved. Carcinomatous serum gives various reactions, as Ishiwara has frequently demonstrated in the laboratory. The sera in the first day after the implantation showed normal conditions in the animal, which continued 15 to 20 days, although the tumour had reached the size of a hazel nut, and not before the 30th day was the serum reaction positive.

NON-OPERATIVE CANCER.

At the medical and scientific meeting, Prof. Czerny opened the proceedings with a lecture on the treatment of cancer without calling in the aid of surgery. He said he knew of no specific, although every year produced a number of these wonderful drugs. Every discoverer found his remedy infallible, but time only proved it to be worthless. There were, however, some drugs put before us which did improve the patient, and ought to be considered; even though they did not cure they might bring about a pause in the progress of the disease. This was an important subject, as 50,000 every year in Germany died from cancer, while it is estimated that 100,000 cancerous patients moved amongst us. As no specific drug can be put forward, the operative treatment is still recognised, although the so-called toxin and immune therapy have been applied with a certain amount of success. In recent times chemo-therapy has gained some favour from the successful experiments on animals. It has long been recognised that carcinoma and sarcoma are

spread in the body by means of circulation, and might be attacked through the stomach and bowel by some chemical process. Professors Neuburg and Kaspari have attempted this with what they term "tumorauffensubstanz." Professors Wassermann and Kaysser have recently experimented on tumours in mice with a combination of seleneosin by injecting it as near the site of disease as possible, so that the metallic salt may be absorbed by the diseased cells, and thus act on the nucleo-globulin. The morbid tissue becomes engorged with blood, the pathological cells break down, and healing of the part rapidly takes place. The danger of this treatment is that the poisonous dose lies so near the healing dose that it has been dangerous to try it on the human body. Neuburg and Kaspari have been working in the same direction with a combination of copper and tin, while Tauber and Gers have been using a colloidal combination with favourable results. Linden and Strass have also obtained good results with copper and lecithin in cancer as well as tuberculosis. Werner has met with considerable success with a combination of cholin salts. The old arsenic remedy has been revived by Ehrlich Hata in his salvarsan treatment under neo-salvarsan, which certainly improves the condition, but little more can be said of it. The Röntgen therapy may be shortly disposed of by saying it is very doubtful in its results.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

EDINBURGH.

MEDICAL AND DENTAL DEFENCE UNION.

At the completion of the 10th year of its existence the Scottish Medical Defence Union is in a strong financial position. In May, 1903, its reserve fund was only £135, or 5s. 9d. per member; this year it stands at £2,535, or £2 1s. 8d. per member. This is a considerably higher figure than that of other similar associations and justifies a complete sense of security against all possible contingencies. The membership now stands at 1,215, and there is a balance on the year's working of £311. The outstanding feature of the year's working has been the exceptionally large number of claims made against members, only a few of which, however, resulted in litigation. The Council continues the policy it has always adopted: If, after consideration of the facts, the position of the member is deemed to be sound, an uncompromising attitude is taken up, and the knowledge that the Union will not pay money to settle troublesome claims and save litigation has in many cases deterred agents from taking further proceedings. Notwithstanding this, lawsuits have been numerous and have occurred in connection with every department of professional work. Practitioners holding public appointments have been subjected to an extraordinary amount of vexatious litigation—cases having arisen out of asylum work, hospital work, public works appointments, friendly society appointments, parish work and others. The Council report that no case presented to them for defence has been refused, and all defended have been successful. The Indemnity Insurance scheme has been extensively taken advantage of by members, as also has the right of applying to the Council or its solicitor for advice on matters of professional difficulty. Altogether, the Union has completed a most satisfactory year's work and is in a most flourishing condition.

GLASGOW.

INSTALLATION OF THE LORD RECTOR.

On Wednesday night, December 4th, the undergrads of Gilmorehill had an opportunity of expending some of the superfluous boisterousness which is apparently a characteristic of their composition. Of course, there had to be an excuse of some sort for the display, and as a rule that is not hard to furnish when the Gilmorehill youths desire to have a night out. The excuse on this occasion was the arrival in the city of their Lord Rector, the Right Hon. Augustine Birrell, M.P., for his installation on the following day, and in accord-

ance with custom the distinguished visitor was escorted to the University by a torchlight procession, which had all the picturesqueness of a fancy-dress parade—a department in which the student shines to advantage. And the Undergrads turned out in force. After the self-elected guard of honour, flourishing their torches, had seen their Lord Rector safely housed in Principal MacAlister's residence at the University the fun commenced, the students devoting the remainder of the night to the task of enlivening the principal streets of the city, but good humour was all-prevailing, and many comical sights were seen. The next day (Thursday) in St. Andrew's Hall the time-honoured custom was observed when the occasion was the address by the Lord Rector. There was a large attendance of students and of the general public, who were admitted by card. The presence in the audience of the red academic gown lent a pleasant sartorial touch to the assembly, and during the interval of waiting for the proceedings to commence there was the singing of the students' choruses and the shouting of student tags, which kept the singers themselves and the public in the best of humour, and the threat of Suffragette interruption lent an added touch of interest to the gathering.

The first business was the conferring upon the Lord Rector of the honorary degree of LL.D. by Principal Sir Donald MacAlister, who presided. Mr. Birrell signed the oath of office and was invested with the robes of office and installed as Lord Rector.

On rising to address his audience, the Lord Rector was hailed with "He's a jolly good fellow," and on continuing his address had not uttered many words when a lady in the side gallery of the platform rose and shouted, "You have not given votes to women." She was immediately hustled out by the vigilant and vigorous stewards. This was followed by several further interruptions with similar expulsions.

The Lord Rector then made a fresh effort with his address on "Thoughts and Deeds." Scarcely, however, had he got beyond the explanatory stage when another lady's voice was heard in the balcony, and on this interruption the Principal intervened, with better results for a time.

Mr. Birrell next made reference to the question of the popular election, incidentally thanking the students for doing him the honour of electing him their Lord Rector.

"What do we mean when we own to the fascination of great events?" was the query which the Lord Rector next set himself to answer. In characteristic manner he answered the question. His address, as usual, was mainly of an academic character, but it was lightened by many felicitous phrases worthy of the author of "Obiter Dicta."

If he were once again young, continued the Lord Rector, he would not depend upon his reading upon any traditional period, or upon any particular crisis, but try to be content to lead the life of his own time, sharing to the full its thoughts and speculations, without recklessness or levity; not, as were the mediavalists, intimidated with the fear of death, yet with a Johnsonian gravity befitting its ever-nearing approach. He appealed to them to think seriously, for the times we lived in were serious. It was the minds of men, and not blind fate, that wove the destiny of the human race.

Mr. Ian D. Grant, president of the Student's Union, proposed a vote of thanks, and asked the Lord Rector to ask for the undergraduates—and professors—(laughter)—of Glasgow University a holiday tomorrow, which was greeted with ringing cheers, and was subsequently granted by the Principal and members of the Senate.

INCENSED STUDENTS RETALIATE ON SUFFRAGETTE'S ROOMS.

Incensed at the Suffragette interruptions during the Rectorial address, a body of the students, numbering about two hundred, marched on the rooms of the Women's Social and Political Union in Sauchiehall Street, with the intention of wrecking them. Arriving in front of the premises, they attacked the large plate-glass window facing the street, and speedily demolished it with sticks and other weapons. A number of them scrambled through the aperture, and, entering

the rooms, they proceeded to destroy everything they could lay their hands on. Although an attack had been expected by the women suffragists, no preparation had been made to protect the rooms, and the invaders engaged in their task without interference.

VICTORIA INFIRMARY: REDUCTION OF CAPITAL FUND.

The twenty-fifth annual report of the infirmary was submitted to the general meeting of contributors on December 5th, when it was stated that the daily average number of resident patients throughout the year was 254, as compared with 248 last year, and their period of residence was 28.3 days and 27.3 days. The total number of patients treated in the wards was 3,530, as compared with 3,560 in the previous year, being a decrease of 30. At no time during the year were there any vacant beds, the decrease being accounted for by the longer period each patient was in the infirmary as compared with the previous year, and also by some of the wards being closed for a short period whilst being re-painted.

Of the cases treated to a conclusion, 327, or a percentage of 10.02, died; but if 104 cases which were of such a nature that the patient died within 48 hours of being admitted are deducted, the death rate is thereby reduced to 7.02, the corresponding percentage last year being 9.15 and 6.37 respectively. In addition 920 cases of minor accidents were treated surgically.

At the infirmary dispensary for outdoor patients 4,591 individual cases were dealt with, involving 15,282 consultations, and at the Bellahouston Dispensary there had been 10,502 patients, involving 29,827 consultations.

The home at Largs continued a valuable adjunct to the infirmary, and during the year 657 patients had been transferred to it from the infirmary in a state of convalescence, compared with 668 last year.

The Governors regretted that the ordinary income fell short of the ordinary expenditure by £1,033 more than last year, arising to a considerable extent from the large increase in the price of coal during the long-continued strike last spring.

The total ordinary expenditure for maintaining the infirmary, Bellahouston dispensary, and the Convalescent Home was £10,500 15s. 9d., the ordinary income amounting to £12,478 13s., showing the very large deficit of £7,022 2s. 9d.

The sum of £4,933 9s. 2d. had to be taken from invested capital, which would entail a reduction of about £200 a year in the revenue from investments. The Governors earnestly appealed to the citizens of Glasgow and neighbourhood for increased support.

PUBLIC HEALTH SERVICE IN RELATION TO THE INSURANCE ACT.

Dr. A. K. Chalmers, Medical Officer of Health for the City of Glasgow, delivered a lecture a few days ago at the University in connection with the Glasgow School of Social Study and Training, taking as his subject "The Relation of the Public Health Service to Private Medical Service in Relation to the Insurance Act." Dr. Chalmers referred to the provisions of the Act dealing with tubercular diseases, and pointed out that it was possible that medical benefits might become available for every period of life. The prevention of disease in the mass was, at the best, a negative quantity, and must needs be supplemented by the promotion of a healthy vigour in the individual. This was only able to be accomplished by the care of the individual from infancy onwards, the extension of the field of preventive medicine over the whole period of infancy and the school ages constituted a frank recognition by the State that positive effort to promote the rearing of healthy citizens must be regarded as among its first duties.

The Mental Deficiency Bill was a frank admission that the forms of mental defect with which it dealt were in the main truly hereditary, and could be prevented only by segregating the generation in which they appeared. Susceptibility to particular forms of communicable disease was no measure of physical fitness or unfitness. It was not the unfit who were selected as the victims of an epidemic of enteric fever, but those who were susceptible to this particular organism, and were unfortunate enough to imbibe it in

sufficient quantity. The successes of preventive medicine had been almost, if not exclusively, won in the field of environment. They had been won, not in defence of Nature's laws, but from man's perversion of them.

Further generalisations were given, and it was pointed out that if the individual patient was to benefit by them, their application must be thought out and directed by the general practitioner.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

TRADES UNIONS AND DOCTORS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If you will turn to the July number of *The Review of Reviews* you will find there an article headed WANTED: SANE TRADE UNIONISM. You will also note a "sub-heading," "If this is Trade Unionism—End it."

If what we have read during the past week in the Press is trade unionism, then the sooner it is mended or ended the better.

The enclosed cutting is what I refer to.

"TRADES UNIONS AND DOCTORS.

"The Executive Board of the General Federation of Trade Unions for National Insurance and Friendly Society purposes passed a resolution protesting against the continued attempts of the medical profession to exploit the Insurance Act and to avoid any semblance of control by insured persons or their representatives, and urging upon the Government the need for an immediate settlement of the dispute concerning medical attendance by the creation of a State Medical Service or by the transference to credit of approved societies of those amounts last offered for medical attendance and medicine, 'in order that neither approved societies nor their members may suffer any further disadvantage or handicap through the refusal of the medical profession to accept the more than generous terms now offered.'

"Dr. Esmonde, M.P., in an open letter to general medical practitioners on the Insurance Act question, urges them 'to consider the welfare of the nation at large, and to free their minds from political or personal prejudice,' and suggests certain questions that might be answered, these relating to the capitation grant, free choice of doctors, and local administration."

Up to this I have always understood that the aim of trade unionists was to procure a living wage and reasonable conditions of service for workers. Is it not for these very principles we medical men are fighting? Hence, one would imagine the very last people to find fault with us for doing so would be trade unionists.

How was it that we, during the coal strike, did not pass a resolution calling on the Government to organise a military corps of miners "in order that we might not suffer any further disadvantage or handicap through the refusal of the miners to accept the more than generous terms offered"? Evidently, nowadays, what is sauce for the goose is not sauce for the gander. The Trades Unions have taught us the principles of the game. We are playing it in a sane manner, and thereby hope to bring some people to their senses.

I am, Sir, yours truly,

CECIL J. CORBY.

Summerhill, Meath, November 30th, 1912.

THE FEEBLE-MINDED BILL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—To-day's papers contain the news that the Mental Deficiency Bill, after safely passing through every vital stage before the Standing Committee charged with its consideration, has now been shelved on the ground that in view of the mass of controversial legislation before them, the Government are powerless to pass it through the House during the present Session. This may mean a delay of years in

bringing into operation a law the urgent necessity for which has been demonstrated, and which has been pleaded for by every authority having valid claim to be heard on the subject. I am only one among many thousands who on these questions have no politics. We welcome real measures of social reform from whatever party emanating, and we deeply deplore the necessity of putting off such measures to give precedence to questions of high policy which do not offer remedies for the social diseases upon the cure of which national salvation depends. Home Rule, Tariff Reform, Disestablishment of the Church, and re-construction of the House of Lords may all be questions, the solution of which are urgently called for, but they are none of them so urgent as measures like the unfortunate Bill about which I write.

What a condemnation of our methods, and what a disappointment to social reformers this represents! Just consider the importance of legislation for the feeble-minded. We learnt from the Royal Commission that over 40,000 of the children in elementary schools, over one-fifth of the inmates of workhouses, one-tenth of the prisoners, one-half of the girls in rescue homes, one-tenth of the tramps of the country, and two-thirds of the inmates in homes for inebriates are mentally defective. That is the population with which the Bill seeks to deal. What about the public opinion behind it? Very many local authorities, Education Committees, Asylum Committees, and Boards of Guardians have urged upon the Government the need for immediate legislation. Philanthropic and charitable societies, agencies for the rescue and protection of children, girls, and women; in fact, all bodies devoted to social work have combined in favour of the Bill. In the meanwhile local authorities are hesitating as to taking up or increasing optional provision for the training of the feeble-minded, on the ground that legislation has been long promised and is absolutely essential before any lasting way of protecting the feeble-minded can be found.

Loss of measures of this kind is largely due to the deplorable fact now so prominent that the medical profession is almost completely lacking in political influence, and its counsel in matters of State has no value in the eyes of our legislators. My official position inclines me to veil my identity, and beg to be allowed to subscribe myself,

Sir, yours truly,

COUNTY MEDICAL OFFICER.

December 7th, 1912.

THE PROSPECTS OF MEDICAL LAW REFORMS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It must be with surprise, as well as regret, that readers will see Mr. Sewill's pessimistic statement in your issue of to-day, November 20th, on the above-named subject. He now declares his belief that all chance of legislation to mitigate existing abuses has been destroyed by recent events. It is not long ago that he wrote to the effect that the case for medical law reform was overwhelming, and needed only stating in a sufficiently authoritative fashion to compel the attention of the Legislature. Those of us who have been working to promote the end in view, and who do not feel inclined to give up the fight without very good reason, would be glad to have a fuller explanation than is afforded in the letter I refer to.

I am, Sir, yours truly,

AN OBSCURE PRACTITIONER.

December 9th, 1912.

OBITUARY.

PROFESSOR LYNHAM, GALWAY.

It is with great regret that we record the death of Dr. John Isaac Lynham, Professor of Medicine at University College, Galway. He was 62 years of age, and his illness was known to be serious for several days before his death.

Dr. Lynham was educated at Queen's College, Galway, and graduated M.D. with a gold medal in the old

Queen's University in 1875. Four years later he was appointed Professor of Practice of Medicine in his old school, and in 1893 he became Bursar of the College. These posts he retained to the time of his death. For many years he was a Fellow of the Royal University and one of the examiners in medicine for that body. He was also Physician to the County Galway Hospital. Lynham was therefore, for the past thirty years, brought into intimate contact, both as teacher and examiner, with successive generations of Irish medical students. He was a careful and painstaking teacher and a conscientious and fair examiner. Old Q.C.G. men all over the world will hear the news of his death with keen regret. By his colleagues he was held in deep personal affection.

His funeral took place last Thursday. The students of University College, in cap and gown, walked immediately behind the chief mourners. All the professors, in their gowns, followed, and the procession was one of the most imposing ever seen in Galway. Hundreds of the townspeople were present, and all the shops were closed as the funeral passed through the town to the new cemetery at Prospect Hill.

DR. WALTER BERNARD, LONDONDERRY.

THE death took place at Buncrana, County Donegal, recently, of Dr. Walter Bernard, aged 85, one of the oldest medical practitioners in Ireland. Dr. Bernard obtained his qualification of M.R.C.S. of England just 60 years ago. He was a fellow of the Royal College of Physicians of Ireland since 1876. He was Surgeon-in-charge of the Second Division Army Works Corps through the Crimean War, and received high commendation for his bravery in grappling with the cholera epidemic in the British lines. On the voyage out he swam after, and saved the life of, a member of the Army Works Corps, who was carried away by the current when bathing in the Dardanelles. For this Dr. Bernard received the honorary silver medal of the Royal Humane Society. He held several appointments in Londonderry, where he practised for many years. He published some years ago a volume of reminiscences.

JOSEPH MORETON, M.D., OF MIDDLEWICH.

A FEELING of deep grief was occasioned in the little town and ancient borough of Middlewich, Cheshire, when it became known that Dr. Joseph Moreton, of "The Beeches," had passed away. Deceased, who was 37 years of age, was the youngest son of Mr. T. B. Moreton, J.P., of Hartford. He had been in delicate health for a long time, but had managed to find strength of a sort to carry on his professional work. Ten days before his death he had an attack supposed to be of influenza; this was followed a few days later by heart failure, and he passed away on Friday, the 29th ult.

In his youth he attended the Victoria College, Congleton, where he took his degree of Bachelor of Science in 1895. He subsequently went to the Victoria University, Manchester, where he was highly successful as a student, and four years later passed the examination entitling him to the degrees of M.B. and B.Ch. with first-class honours. He was the author of "Treatment of Tuberculosis," which was the thesis for his degree of M.D., gained in 1903. Amongst his other first-class successes were the Dalton Natural History Exhibition, the Dauntsey Medical Scholarship, the Platt Physiological Exhibition (Junior and Senior), the University Scholarship in Medicine, the Dunville Surgical Scholarship, the Bradley Scholarship in Clinical Surgery (Manchester Royal Infirmary). Among his earlier appointments were House Surgeon to the Manchester Southern Hospital for Women and Children, House Surgeon to the Manchester Royal Infirmary, and Assistant Demonstrator of Anatomy in Owen's College. Not long after he was threatened with phthisis, and went to St. Moritz, then to sea for a time, later to South Africa, where he spent three years, and came back with his health re-established.

He commenced practice in Middlewich in 1905, where he continued to the time of his death. In the

same year he married May, eldest daughter of Mr. Ezra Gandy, Acton Bridge, Cheshire, for whom much sympathy is felt in her sad bereavement.

His most important medical appointment was that of Medical Officer to the Isolation Hospital, Davenham, a position he held from the time of its opening to his death.

SPECIAL REPORTS.

RIGHT HON. DR. COX AND THE MEDICAL PROFESSION.

THE following correspondence has taken place between the Hon. Secretary of the Dublin Local Medical Committee and the Right Hon. Dr. Michael F. Cox:—

November 13th, 1912.

To the Right Hon. M. F. Cox, M.D.

DEAR SIR,—With reference to our brief conversation a few days ago, relative to the view you expressed at a meeting of the Advisory Committee held on October 30th, and reported in the *Evening Telegraph* of November 4th, I beg to amplify the remarks which I then made, and I deem it necessary to do so because it would appear that your views have been misinterpreted by a considerable number of your professional brethren who have been discussing them with me in my official capacity. I think, therefore, that in order to avoid any misunderstanding, the points at issue might with advantage be elucidated. More especially having regard to the prominent position which you hold in our profession any views which you give expression to are likely to be considered by the public as reflecting the opinions of a large section of Irish medical men.

First, with regard to the extension of medical benefits to this country: The profession in Ireland and in England have agreed to act loyally by each other in any arrangement with the Government which might be arrived at, so that if medical benefits be extended to Ireland they can be accepted only upon the same conditions as obtain in England.

Since this is so, the extension of the medical benefit clause of the Act cannot be made to include the family of the insured, as you suggested at the meeting. It is unreasonable to expect that in Ireland a doctor should give attendance to the insured and his family for the same fee which in England is considered inadequate remuneration for attendance upon the insured alone—the women and children in a family require far more medical attention than the men.

Further, having dissociated yourself from the policy of the B.M.A., with which most of your professional brethren have identified themselves, you are reported to have said that you have taken no part in recrimination or in acrimony, and that your hands were clean, your tongue was clean, and your pen was clean in this matter. This statement seems to imply that the profession or those acting for them have engaged in such practices, and that their actions were deserving of censure.

Permit me to say that if this interpretation is correct, and it is not the intention of those who read this meaning into what you have said to misrepresent you (your statement at the meeting was accepted as a repudiation of the policy of the profession), that neither in Dublin nor elsewhere in Ireland have the profession acted in any but an honourable and dignified manner, although they have been subjected to much provocation through letters appearing in the daily papers and comments in one weekly journal. Despite all this invective, the profession has kept its temper, and more especially does this apply to the Dublin County Borough Local Medical Committee. It is not the fault of my Committee that a conference to discuss the local dispute with the Friendly Societies was not held, because when a conference was suggested, my Committee expressed their willingness to participate in it.

I am, yours faithfully,
(Signed) MAURICE R. J. HAYES,
Hon. Sec.

26 Merrion Square, Dublin,

November 14th, 1912.

DEAR DR. HAYES,—I received your letter this morning, and hasten to answer it. I am amazed that such a misconception should have been put upon my words. I could not have thought it possible.

On the occasion referred to, words of offence and insult were used towards our profession, and I found myself accused of having fomented strife, when I could have procured a peaceful settlement. I repelled the aspersions cast upon our profession, and recalled the sacrifices made, even of life itself, by many members of the profession. I deprecated, and deplored, the use of bitter and acrimonious language—I pleaded for conciliation not conflict. Of the accusation made against myself I said that my hand and pen and tongue were clean; I spoke for, not against, the profession to which I have the honour to belong, and from whose honour and fame I have never detracted. As for the Advisory Committee, I was appointed not by the British Medical Association, but by the Irish Insurance Commissioners. I did not seek appointment. I have not resigned, because I thought I might be of more use to our profession, and our people by remaining on, and because I did not wish to seem to cast a vote against a vital measure of a Government pledged to Home Rule for Ireland.

As for the extension of medical benefits to Ireland, that I thought was demanded at the beginning. Is it now repudiated?

I laid down no terms, but I expressed the opinion that wives and children are no less deserving of care than husbands or even fathers.

I further expressed the opinion that when Home Rule comes, as come it must, one of the first measures of a Home Rule Parliament will be a thorough reform of the Poor Law system—which would settle the entire question of medical service in Ireland, on terms fair to the profession, and just to the people, whose welfare is our greatest ambition.

I am, dear Dr. Hayes, faithfully yours,
(Signed) MICHAEL F. COX.

November 25th, 1912.

The Right Hon. M. F. Cox, M.D.

DEAR SIR,—I placed the recent correspondence which passed between us relative to your speech at the meeting of the Advisory Committee before my Committee at their last meeting, and I amplified the explanation in your letter by repeating the statements which you made to me in conversation.

I am directed to state my Committee were very pleased to note that you repudiate the interpretation which has been put upon the speech to which I drew your attention, and that your views with regard to the just claims of the profession are not at variance with those of your fellow-practitioners.

I am also directed to request your permission to publish this correspondence in the Press, as my Committee feel assured that you would not wish the public to misinterpret your views. That they have done so is clear from the interpretation put upon them by Mr. J. D. Nugent in his speech as reported in the *Freeman's Journal* of the 21st inst.

I am, yours faithfully,
(Signed) MAURICE R. J. HAYES,
Hon. Sec.

REVIEWS OF BOOKS.

THE CLINICAL PATHOLOGY OF SYPHILIS. (a)

THE author commences with the methods of detecting *spirochæta pallida*, and gives the latest views on the subject of re-infection and immunity. He next deals with syphilitic anæmias, and, although only nine pages are devoted to them, the subject is fully

(a) "The Clinical Pathology of Syphilis and Parasyphilis and its Value for Diagnosis and Controlling Treatment." By Hugh W. Bayly, M.A., M.B.C.S., L.R.C.P.Lond., Clinical Pathologist to the London Lock Hospitals. Crown 8vo. Pp. XIV. and 194. Plates three. Figures in text, 22. London: Baillière, Tindall and Cox. 1912. Price 5s. net.

discussed in all stages of acquired and hereditary syphilis.

The Wassermann reaction, the advantages of the original *technique*, and later modifications are all fully discussed. Considerable space is devoted to the nervous system, and the diagnostic value of the Wassermann reaction in the examination of the cerebro-spinal fluid is given. Special praise is due to the masterly handling of syphilitic nephritis. The whole subject of salvarsan, its administration and the advantages derived from it are gone into thoroughly, and the author suggests the advisability of combining salvarsan and mercurial treatment.

In a brief summary it is stated that general paralysis is the only one of all syphilitic affections in which a negative Wassermann is of definite clinical value, and that the cases that are benefited by treatment are few. A negative Wassermann cannot put tabs out of court.

The Wassermann is most valuable in diagnosing latent syphilis. In suspected hereditary syphilis, a negative Wassermann is strongly against the lesions being due to syphilis.

The book supplies all the information that is required by the practitioner and pathologist. Being well-bound in leather, it would be capable of resisting the rough usage of laboratory work.

A SYSTEM OF TREATMENT. (a)

VOLS. I. and II. are concerned with general medicine and surgery. Dr. Mitchell Bruce deals with the principles of treatment in the opening chapter of Vol. I., and comments upon the important points so as to bring out the special value of each example. The management of the sick room is ably discussed, and will be found to give confidence to the nurse, with a number of valuable directions from the pen of Miss McCall Anderson, while the general hygiene and care of infants and young children by Dr. Eustace Smith, of the East London Hospital for Children, gives a well-considered and exhaustive survey of that department of medicine in which he is so deeply interested. General treatment of infectious diseases are considered by Dr. Foord Caiger and Dr. Cuff, and they emphasise the importance of giving diphtheritic serum early, even although the diagnosis be somewhat doubtful. The treatment of typhoid fever by Colonel Reid Roberts will give the practitioner much aid in the directions and various methods in regard to the management of this disease of defence, not of attack, and the complications likely to be met with are ably discussed. To the forefront is the space which has been allocated to the treatment of pulmonary tuberculosis in four valuable articles, the author's knowledge in respect to sanatoria, tuberculin, graduated labour, and the induction of artificial pneumothorax is most clearly described, along with the class of patient that is most suitable for the different treatment. The illustrated paper by Sir Wm. Bennett on varicose veins and varicocele gives a very excellent account of the operative procedure. Dr. W. Hale White does not advocate the routine methods of administering expectorants during pneumonia, but for the heart failure usually accompanying this disease he considers pituitary extract to be a better drug than adrenalin.

Vol. II.—Diseases of the blood and blood-forming organs are discussed by Dr. Herbert French and Prof. Murray, who have summarised the treatment of a difficult subject in a most explicit and comprehensive manner. Mr. P. Lockhart Mummery's contributions are chiefly concerned with the large intestine and rectum; and Mr. A. W. Mayo Robson deals in a very able manner with the affections of the stomach and pancreas. Mr. Jonathan Hutchinson, dealing with affections of the tongue, is a very valuable asset to this volume. Mr. J. W. Thomson Walker, in the treatment of kidney affections, gives a terse and adequate account of its various sections; and Mr. T. Crisp English presents to the practitioner, busily engaged

with other subjects, in treatment of affections of the breast, a mine of information in the minimum of space.

Vol. III. deals with the special subjects of medicine, including, amongst others, affections of the eyes, nose, ear, throat, skin diseases and dental surgery, while hypnotism, serum and vaccine therapy, electric medication massage, Bier's treatment, are all found to be adequately dealt with. A very useful chapter on "Anæsthetics" is that written by Dr. J. Blumfeld, whereby the dangers and difficulties which beset the anæsthetist are satisfactorily discussed. Mr. Herbert F. Waterhouse is a valuable exponent of Bier's treatment, but is of the opinion that it is a neglected remedy in this country; and the late Dr. William R. Huggard's article on climatology should be read if only to assist the practitioner in the selection of localities for his patients. Dr. Gustav Hamel, in a useful article on massage, and Dr. A. Primrose Wales, on mechanical vibration, are deserving of praise for their interesting accounts and methods, which are fully explained. As specially interesting in present circumstances are the number of disorders, along with the most minute description of manipulation with which Dr. John F. Woods is able to combat by the aid of hypnotism; and the practice of serum therapy and vaccine therapy, by Dr. Arthur Latham, is full of interest, with articles on each individual organism by capable authorities is an advance in the right direction.

Tropical fevers are well to the front, and the reader will have little difficulty in acquiring such knowledge as he is likely to need in this country.

Mr. William Milligan is an able contributor, and offers many valuable suggestions out of the ordinary beaten track in his essays on diseases and affections of the ear.

Vol. IV. is concerned with the treatment of the obstetric and gynaecological standpoint. When it is remembered that the contents are written by Dr. J. W. Ballantyne, Mr. John Bland-Sutton, Dr. E. Hastings Tweedy, Mr. Victor Bonney, Dr. Comyns Berkeley, to mention a few, our expectation is that a large amount of information will be forthcoming, and in this we are not disappointed. The general management of pregnancy, puberty and the menopause is especially worthy of note, and along with the medical side of treatment in the case of pregnant women, forms an important and interesting treatise.

Dr. Darwell Smith deals with the management of contracted pelvis in a masterly manner. Rupture of the uterus, by Dr. Cuthbert Lockyer, gives an accurate idea of what treatment to adopt, along with a vast amount of references on his subject. The second half of the book brings the treatment of gynaecology a stage nearer to the door of the general practitioner, and the short articles of Mr. John Bland Sutton are directly to the point at issue without any super-abundant packing.

Dr. G. Bellingham Smith deals with diseases of the bladder and urethra in a thoroughly practical and scientific fashion.

The System of Treatment as a volume is admirably arranged, and the sketches that illustrate the various situations are clear and accurate. The volume is presented in an attractive format, and should receive a welcome from the general practitioner, the specialist and others interested in medicine as being full of fact and solid information. The list of authors are in the very forefront of their own speciality, and no doubt exists of their competency to deal with his subject. A great advantage is that all the volumes are published at the same time, and each volume is provided with a full and complete index, not only for its own book, but also for the series, and the whole volume reflects credit both on the editors and publishers.

STUDIES IN CLINICAL MEDICINE. (a)

Most of these studies have already appeared in the medical magazines. Their subject matter is widely diverse, and the advantage of having them collected in a single volume is not altogether obvious. At the same time we are bound to admit that we have derived both

(a) "Studies in Clinical Medicine." By C. O. Hawthorne, M.D. Pp. 441. London: John Bale, Sons and Danielsson, Ltd. 1912.

(a) "A System of Treatment." In Four Volumes. Edited by Arthur Latham, M.D.Oxon., F.R.C.P., Physician to St. George's Hospital, and T. Crisp English, B.S.Lond., F.R.C.S., Senior Assistant Surgeon to St. George's Hospital. London: J. and A. Churchill. 1912. Price £4 4s. net.

pleasure and profit from a perusal of the book. The article on the cerebral and ocular complications of anæmia is decidedly useful, and there is a most helpful "clinique" on septic endocarditis. We have seen just such a case as the author describes where there was little fever, and intrinsic cardiac signs were not much in evidence. There is much useful information on a variety of common ailments, and there are interesting essays on sudden greyness of the hair and on the Pharmacopœia. Altogether the book is a delightfully written medical miscellany.

EXPERIMENTAL PHYSIOLOGY. (a)

THIS volume is based on the author's directions for class work in "Practical Physiology." In its present form it is a considerable improvement on the latter work. Not only have the directions been re-written and the diagrams been re-drawn, but we venture to think that in several instances the exercises have been better arranged. Much new matter has been added in the form of experiments illustrative of the physiology of the circulation, central nervous system, special senses, etc. The directions are clearly given, and the book should find favour with teachers of physiology and those who have to pass examinations on the subject.

AMONG the Christmas annuals for 1912 that have reached us may be mentioned that of our contemporary, *Truth*. Always humorous, incisive, sarcastic; the present issue is one of its most successful and entertaining ventures in versification that we remember. The whole literary output is after the manner of the author of "Ingoldsby Legends," full of amusing quips and shafts at the powers that be. The coloured plates too, in which Mr. Lloyd George's physiognomy is a prominent feature, will attract attention, whilst that entitled "Two Sides of Holloway," wherein the prisoner of low degree is depicted with the prison warder, with "skilly," as her only visitor, and the militant suffragette is allowed a physician to see after her health, and champagne as an item in her daily menu, will necessarily evolve mingled criticism according to the views held of "Votes for Women."

NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:—

- APPLETON, D., AND CO. (London).
The Surgical Diseases of Children. By W. F. Campbell, A.B., M.D., and Le Grand Kerr, M.D. Illustrated. Pp. 693. Price 25s. net.
Diseases of Children. By Benjamin Knox Rachford. Pp. 783. Price 25s. net.
- ARNOLD, EDWARD (London).
International Medical Monographs. General Editors: Leonard and Lead Absorption. By Thomas M. Legge, M.D.Oxon., D.P.H.Cantab., and Kenneth W. Goadby, M.R.C.S., D.P.H.Cantab. Price 12s. 6d. net.
The Carrier Problem in Infectious Diseases. By J. C. G. Ledingham, M.B., D.Sc., and J. A. Arkwright, M.D. Pp. 319. Price 12s. 6d. net.
The Protein Element in Nutrition. By Major D. McCay, M.B., B.Ch., B.A.O., M.R.C.P., I.M.S. Pp. 216. Price 10s. 6d. net.
Forensic Medicine and Toxicology. By C. O. Hawthorne, M.D. Third Edition. Pp. 344. Price 6s. net.
- BAILLIÈRE, TINDALL, AND COX (London).
Papers on Psycho-analysis. By Ernest Jones, M.D.Lond., M.R.C.P.Lond. Pp. 432. Price 10s. 6d. net.
From Cloud to Sunshine: Algiers and Algeria. By Alfred S. Gubb, M.D. Pp. 114. Price 2s. net.
Lectures on Clinical Psychiatry. By Emil Kraepelin. Authorised Translation from the German Edition, revised and edited by Thomas Johnstone, M.D.Edin., M.R.C.P. Lond. Third English Edition. Pp. 368. Price 10s. 6d. net.
- Aids to Gynecology. By S. Jervois Arons, M.D.Edin., M.R.C.P.Lond. Fifth Edition. Pp. 124. Price 2s. 6d. net.
- BALF, JOHN, SONS, AND DANIELSSON, LTD. (London).
The Internal Secretory Organs: their Physiology and Pathology. By Professor Dr. Arthur Biedl, Vienna. With an Introductory Preface by Leonard Williams, M.D., M.R.C.P. Translated by Linda Forster. Pp. 586. Price 21s. net.
- CHURCHILL, J. AND A. (London).
Year-Book of Pharmacy. Comprising abstracts of Papers contributed to British and Foreign Journals with the Transactions of the British Pharmaceutical Conference held in Edinburgh, July, 1912. Edited by J. O. Braithwaite, and Horace Fenimore, B.Sc. Pp. 644. Price 10s. net.
Elementary Clinical Pathology for Nurses. By George

- Herschell, M.D.Lond., and Richard Weiss, Ph.D., M.A., F.C.S. Second Edition. Pp. 30. Price 1s. net.
Transactions of the Ophthalmological Society of the United Kingdom. Vol. 32. 1912. Price 4s. net.
- FFIELD, A. C. (London).
The Nature of a Woman. By J. Lionel Tayler, M.R.C.S., L.R.C.P. Pp. 186. Price 3s. 6d. net.
- GRIFFIN, CHARLES AND CO., LTD. (London).
Clinical Medicine: A Manual for the Use of Students and Junior Practitioners. By Judson S. Bury, M.D.Lond., F.R.C.P., and A. Ramsbottom, M.D., M.R.C.P. Illustrated. Pp. 530. Price 17s. 6d. net.
- HAZELL, WATSON AND VINEY, LTD. (London).
Hazell's Annual for 1913. A Record of the Men and Movements of the Time. Edited by Hammond Hall. Pp. 592.
- HIRSCHFELD BROS., LTD. (London).
The Illness and Death of Napoleon Bonaparte. (A Medical Criticism.) By Arnold Chaplin, M.D.Cantab. Pp. 112. Price 2s. 6d.
- JACK, T. C. AND E. C. (London and Edinburgh); DODGE PUBLISHING CO. (New York).
Hypnotism and Self-Education. By A. M. Hutchison, M.D. Pp. 92. Price, cloth, 6d. net.
The Baby: A Mother's Book by a Mother. By a University Woman. Pp. 94. Price, cloth, 6d. net.
Marriage and Motherhood: A Wife's Handbook. By Hugh S. Davidson, M.B., F.R.C.S.Edin. Pp. 94. Price, cloth, 6d. net.
- LEWIS, H. K. (London).
Surgery of the Brain and Spinal Cord. Based on Personal Experiences. By Professor Fred Krause, M.D. English Adaptation by Dr. Max Thorek (Rush M.C. Univ. of Chicago). Vols. 2 and 3. Price 30s. each net.
Vaccine Therapy: Its Theory and Practice. By R. W. Allain, M.D., B.S.Lond. Fourth Edition. Pp. 444. Price 9s. net.
- LONGMANS, GREEN AND CO. (London).
Geometrical Optics. By Archibald Stanley Percival, M.A. M.B., B.C.Cantab. With Diagrams. Pp. 132. Price 4s. 6d. net.
- MACLEHOSE, J., AND SONS (Glasgow).
A Manual of Immunity. For Students and Practitioners. By Elizabeth T. Fraser, M.D.Glas. Pp. 199. Price 5s. net.
- MACMILLAN AND CO., LTD. (London).
Diseases of the Liver, Gall-Bladder, and Bile-Ducts. By Humphry Davy Rolleston, M.A., M.D.Cantab., F.R.C.P. Pp. 811. Price 25s. net.
- OXFORD UNIVERSITY PRESS (London).
Manual of Operative Surgery. By H. J. Waring, M.S., M.B., B.Sc.Lond., F.R.C.S. Fourth Edition. Pp. 778. Price 12s. 6d. net.
Cunningham's Manual of Practical Anatomy. By the late D. J. Cunningham, M.D. Vol. II. Fifth Edition revised by Arthur Robinson. Illustrated. Pp. 616. Price 10s. 6d. net.
Manual of Medicine. By A. S. Woodwark, M.D., M.R.C.P. Pp. 409. Price 10s. 6d. net.
- PAUL, STANLEY, AND CO. (London).
The Physiology of Faith and Fear or the Mind in Health and Disease. By William S. Sadler, M.D. Illustrated. Pp. 580.
- SAUNDERS (W. B.) COMPANY (Philadelphia).
Nutritional Physiology. By Percy Goldthwaite Stiles. Pp. 272. Price 6s. net.
A Text-Book of General Bacteriology. By Edwin O. Jordan, Ph.D. Third Edition, thoroughly revised. Pp. 623. Price 13s. net.
A Text-Book on the Practice of Gynecology. For Practitioners and Students. By William Easterly Ashton, M.D., LL.D. Illustrated. Fifth Edition, thoroughly revised. Pp. 1,100. Price 27s. 6d. net.

- WRIGHT, JOHN, AND SONS, LTD. (Bristol); SIMPKIN, MARSHALL, HAMILTON, KENT, AND CO., LTD. (London).
Pye's Surgical Handicraft: A Manual of Surgical Manipulations and Minor Surgery. Edited and largely re-written by W. H. Clayton-Greene, B.A., M.B., B.C.Cantab. F.R.C.S.Eng. Sixth Edition. Fully revised and illustrated. Pp. 595. Price 12s. 6d. net.
A Manual of Infectious Diseases occurring in Schools. By H. G. Armstrong, M.R.C.S., L.S.A., and J. M. Fortescue-Briekdale, M.A., M.D. Pp. 150. Price 3s. net.

NEW APPLIANCES.

ARNOLD'S "MOSANA" SANITARY TOWEL.
We have been favoured with a sample of Dr. Degen's sanitary towel for ladies, which seems excellently well adapted for the purpose. On the one hand it is smooth and soft, giving to the outlines of the body, and preventing irritation and discomfort, and on the other hand its pad is thoroughly absorbent, preventing the permeating of moisture and the soiling of the underwear.

(a) "Experimental Physiology." By E. A. Schäfer, F.R.S. Pp. 111. London: Longmans, Green and Co. 1912. Price 4s. 6d.

A combination of wool and an outer covering has been invented which preserves the good qualities of the padding. The latter is covered by a wide mesh net of fine but strong thread in such a way that the facings consist, as it were of wool, which follows closely and smoothly the outline of the body, and for this reason this sanitary towel is said to be exceptionally soft and comfortable in wear, making friction and inflammation impossible. The safety loop of the "Mosana" sanitary towel prevents any accident due to its becoming detached.

This towel possesses not only softness and flexibility, but also the important hygienic properties of Dr. Von Brun's antiseptic surgical wool of which it is largely composed. In addition, the cellular antiseptic wool padding possesses great absorbent power.

No medical man, in short, need hesitate in recommending the "Mosana" sanitary towel to his patients. A special belt for attachment can also be obtained.

Messrs. Arnold and Sons, Giltspur Street, London, E.C., are the manufacturers.

MEDICAL NEWS IN BRIEF.

Organisation of the Profession in Dublin.

THE following resolution was passed unanimously at the last meeting of the Dublin County Borough Local Medical Committee:—"That the Hon. Secretary be requested to draw the attention of medical men in the County Borough who have signed the undertaking to the fact that the terms of the undertaking pledge them not to accept any appointments from societies except through the Local Medical Committee, whether remuneration be by capitation, by fee, or by salary."

Women's National Health Association.

A SPECIAL Council meeting of the Women's National Health Association was held last week in the Theatre of the Royal Dublin Society, Leinster House. The Countess of Aberdeen, President, occupied the chair, and there was a good attendance of members.

Her Excellency said that there were several reasons for holding that meeting. The first was the fact of the completion of the incorporation of the Association, which had been under consideration for a considerable time past, and which had only been carried out that morning. Up to that the Association had no legal status for any course of action which it might take, and each member was liable for any acts of the Association which might afterwards be held to have been indiscreet. Now that the Association was duly incorporated under the Board of Trade all that was changed, and it could enter as an Association into every class of business in its corporate capacity, and individual members got rid of their liabilities, with the single exception of being liable, in the event of the Association being at any time wound up, to the extent of the sum of 10s. at the outside; and as an approved society under the Insurance Act their Society and their members would be represented on the Insurance Committees throughout the country, and make the influence of their experience felt. Her Excellency then detailed the various matters with which the Association proposed to deal in its newly incorporated form, such as the promotion of sanatoria, the establishment of playgrounds, and other matters relating to the public health.

After some discussion as to the holding next year of a Health Week in connection with the work of the Association, the project was approved of, and it was decided to accept the invitation of the Agenda Club to organise a Health Week in Ireland from the 6th to the 12th April, 1913, and Her Excellency was appointed as representative of the Women's National Health Association on the General Committee of the scheme.

Several branches of the activity of the Association came under discussion.

The Hospital Sunday Fund.

At a meeting of the Metropolitan Hospital Sunday Fund at the Mansion House, on Monday last, presided over by the Lord Mayor, it was reported that the col-

lections for the year amounted to £67,972 14s. 3d., an increase of £957 over last year. The collections in the various places of worship had resulted in a sum of £35,866 being collected, this being £1,195 less than in 1911, while the balance was made up by special donations, legacies, and collections. The working expenses amounted to £3,125 7s. 7d., as compared with £3,447 17s. 5d. in 1911. It was arranged that Hospital Sunday for next year should be held on May 25th.

University of London.

A meeting was held at the University on Foundation Day (November 28th), the Principal, Sir Henry Miers, presiding, to consider the question of establishing a Club for graduates, teachers and officers of the University. In the letter convening the meeting it was stated that the Senate, while disapproving of the formation of a social club of which men and women undergraduates could become members, would welcome the establishment of a Club for graduates, teachers and officers, and would be prepared to consider an application for an annual subvention if the premises provided satisfactory accommodation for the meetings and business of Ungraduates' Societies and for other University purposes. A resolution moved by Mr. Wickham Hurd, LL.B., proposing the establishment of a Club on the general lines approved by the Senate was carried unanimously and a Committee was appointed to consider the best means of carrying the resolution into effect, with instructions that the Club should be a members' club in preference to a proprietary club. The Committee are to report to another general meeting.

Royal College of Surgeons in Ireland.

THE following candidates have passed the under-mentioned Examinations, November, 1912:—

Primary Fellowship Examination.—Miss L. M. Ghose, Miss S. Hoashoo, Mr. L. S. Modi, Mr. J. A. Musgrave, and Mr. L. M. Rowlette.

Final Fellowship Examination.—Mr. Moore Betty, Mr. J. L. Bocarro, Mr. T. Crawford Boyd, Miss Ma Saw Sa, and Mr. P. McCartan.

Final Dental Examination.—Mr. Henry Flavell Holmes, Mr. Edward Lanigan, Mr. Kieran McGrath, Mr. William John Marmion, and Mr. Thomas Stanley Sullivan.

Trinity College, Dublin.

THE following candidates have passed the Final Medical Examination, Part II. (Michaelmas Term, 1912):—

Surgery.—Eileen M. Hewitt, Frederick B. McCarter (passed on high marks), Robert Hemphill, Jacobus M. S. Gericke, Walter Crane, Hubert T. Bates, Kenneth K. Drury, William Frier, William P. Croker, Charles D. Goodenough, Jevon H. Powell, Joseph A. Maxwell, Charles W. C. Myles, Richard S. G. Halpin, Robert A. G. Elliott, Bernard G. Quinlan, Oswald C. S. Tandy, Edgar H. Wilkins, William E. Fetherstonhaugh, George J. Meldon, Georgina Revington, Reginald O. Smyth, James A. Small.

Midwifery.—John W. C. Stubbs, Jevon H. Powell (passed on high marks), David H. Hadden, Frederick G. Flood, Mabel A. Dobbin, Theodore W. Allen, William F. Evans, Charles W. C. Myles, Etienne J. Malherbe, Charles J. O'Reilly, John T. Simpson, Edgar H. Wilkins, Thomas F. Breen, Joseph Harvey, Frederick R. Dougan, Reginald H. Jones, Geoffrey A. Hoffman, Hedley Boyers, Joseph S. English.

License in Dental Science.—William G. Kingston.

University of Oxford.

THE following degree has been conferred:—D.M.—W. D. Sturrock, Magdalen.

University of Cambridge.

THE following degrees have been conferred:—

M.D.—H. B. Carlill, St. John's.
M.C.—A. H. Crook, Christ's.
M.B. and B.C.—J. Winterbotham, King's; B. A. Playne, Pembroke; W. H. Cam and A. H. Gosse, Caius.

M.B.—A. H. Crook, D. Embleton, Christ's.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 2ls.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. and pro rata for smaller spaces.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8 Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

M.B. (Brockley).—We quite agree that used tram and bus tickets may be a source of danger to health, especially when, as is too often the case, small children are allowed to collect them from the floor and seats. The suggestion of Dr. Killick Millard, the Medical Officer of Health for Leicester, is a timely one. It consists of dropping the used ticket into a receptacle provided for the purpose on leaving the vehicle.

"THE MEDICAL WHO'S WHO" for 1913.

We are asked by the editors of this Directory to announce that they will be glad to receive the corrected particulars from those members of the profession who have not yet returned them, before the 31st inst., addressed to the publishing offices, 6, Henrietta Street, Strand, London.

Dr. T. F. (I.W.).—Leicithin has been found useful in conditions of gastro-intestinal auto-intoxication, as well as in debilitated states and nervous affections generally.

CREMATION IN SCOTLAND.

THE annual report of the Scottish Cremation Society states that during the year ending on September 30th last there were at the Glasgow Crematorium 44 cremations, as compared with 35 in the preceding year and 26 in the year before. Altogether, since the crematorium was opened, 420 cremations have taken place. There was a financial surplus of £71 last year. The ordinary charge for cremation is £6 6s. The directors of the society believe that there are now evidences of the beginnings of a great forward movement in the adoption of cremation. A special crypt for the reception of urns has been erected in St. Columba's Presbyterian Church, London, and the cremated ashes of the late Bishop of Truro have been deposited in Truro Cathedral. Mr. A. Philip, Panmure Street, Brechin, is one of the branch secretaries of the Scottish society.

HUMOUR OF MEDICAL PRACTICE.

A LITTLE girl once asked a doctor why he put so much water into his medicine. She received the answer "To make it pleasant," to which she retorted gravely, "It does seem a waste of water."

A chemist was once sorely puzzled by a girl's request for "Glory Divine." After some time he found that what she really wanted was "chloride of lime."—Dr. Norman Porritt at Romford.

Ma. W. J. M. (Bournemouth) is thanked for his communication which is marked for insertion.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, DECEMBER 11TH.

HUNTERIAN SOCIETY (St. Bartholomew's Hospital, E.C.)—9 p.m.: Clinical and Pathological Evening.

UNITED SERVICES MEDICAL SOCIETY (Royal Army Medical School, Greenwich).—5 p.m.: Fleet-Surgeon Munday, R.N.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics:—2 p.m.: Throat Operations (Mr. Gillies). 2.30 p.m.: Children's Out-patient (Dr. T. R. Whipple); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 p.m.: Eye Operations (Mr. Brooks).

BROMPTON HOSPITAL FOR CONSUMPTION.—4.30 p.m.: Lecture by Dr. Bosaquet: Affections of the Oesophagus.

THURSDAY, DECEMBER 12TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF BALNEOLOGY AND

CLIMATOLOGY) (1 Wimpole Street, W.).—5.30 p.m.: Paper: Dr. William Bain (Harrogate): The Medical Treatment of Gall-stone Disease.

CHILD STUDY SOCIETY, LONDON (Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.).—7.30 p.m.: Dr. C. S. Myers.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, W.).—8.30 p.m.: Mr. C. W. M. Hope.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Princes of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynaecological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappell). 4.30 p.m.: Lecture: Mr. W. Steuart: Diagnosis by Bismuth X-Rays.

THE NEW LONDON DERMATOLOGICAL SOCIETY (Western Skin Hospital, Hampstead Road, N.W.).—4.30 p.m.: Meeting. Clinical Cases.

FRIDAY, DECEMBER 13TH.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASES IN CHILDREN) (1 Wimpole Street, W.).—4.30 p.m.: Discussion: On the Treatment of Heart Disease in Children (opened by Dr. Edmund Cautley and Dr. James Mackenzie). The following will take part in the discussion:—Dr. John Hay (Liverpool). Dr. C. W. Chapman, Dr. Walter Carr, Dr. Sutherland, Dr. Alexander Morrison, Dr. Poynton, and Dr. F. W. Price.

ROYAL SOCIETY OF MEDICINE (CLINICAL SECTION) (1 Wimpole Street, W.).—8.30 p.m.: Cases by Mr. Ralph Thompson, Mr. Parkes Weber, Mr. T. H. Kellock, Dr. Essex Wynter, and others. Paper: Mr. T. H. Kellock: Pneumonotomy.

MONDAY, DECEMBER 16TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Continuation of discussion on "Interstitial Stasis," by Sir Bertrand Dawson, Dr. James Mackenzie, Mr. Creasy, Dr. Distaso, Mr. Barrington Ward, Dr. Schlesinger, Mr. J. E. Waugh, Mr. Peter Daniel, Dr. Ofenheim, Dr. G. Rowell, and Dr. Wainwright.

Appointments.

COPE, V. ZACHARY, M.D., M.S.Lond., F.R.C.S.Eng., Surgeon to the Bolingbroke Hospital, Wandsworth.

EDMONSTONE, C. G., M.B., B.Ch.Edin., F.R.C.S.Edin., Certifying Surgeon under the Factory and Workshop Acts for Swanscombe District of the county of Kent.

GLENDINING, BAYDEN, M.B., M.S.Durh., F.R.C.S.Eng., Gynaecologist to the Hampstead General and North-West London Hospital.

GRAHAM, G. M., M.B., Ch.Edin., Junior Assistant Medical Officer at the Stirling District Asylum, Larbert.

HOWELL, B. WHITTECHURCH, M.R.C.S., L.R.C.P., House Physician at the Royal Free Hospital.

MIDDLETON, Miss, Clinical Assistant to the Royal Free Hospital

Vacancies.

County Asylum, Lancaster.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and attendance. Applications to the Medical Superintendent.

Middlesex County Asylum (near Wandsworth Common Station, L.B. and S.C.R.).—Third Assistant Medical Officer. Salary £200 per annum, with full board, lodging, etc. Applications to the Medical Superintendent.

State Criminal Lunatic Asylum, Rampton, South Leveaton, Lincoln.—Assistant Medical Officer. Salary £225 per annum, with furnished quarters, coals, light, and attendance. Applications to the Medical Superintendent.

Royal Hospital for Diseases of the Chest, City Road, E.C.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing. Applications to the Secretary.

Caterham Asylum.—Third Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Births.

BEATTIE.—On Dec. 5th, at 3 Ellison Place, Newcastle-upon-Tyne to Dr. and Mrs. Thomas Beattie, a son.

FRASER.—On Dec. 6th, the wife of Capt. F. C. Fraser, I.M.S., of a son.

TARBET.—On Nov. 28th, at Stevenage, Herts, the wife of Peter Rowley Tarbet, M.R.C.S., L.R.C.P., of a son.

Marriages.

BOURNE—HAYWARD.—On Dec. 3rd, at the Wesleyan Church, New Barnet, Alice William Bourne, M.B., B.C., F.R.C.S., to Bessie Winifred, eldest daughter of Mr. and Mrs. G. W. Hayward, of Ingleside, New Barnet.

CHAPMAN—RODGERS.—On Dec. 7th, at St. Stephen's Church, Tonbridge, Raymond John Chapman, M.D., D.P.H., eldest son of the Vicar of the Parish, and Gertrude Madeline Naomi Rodgers, daughter of the late Thomas William Rodgers, Esq., of Belfast.

NICHOLSON—ROBINSON.—On Nov. 15th, at St. Thomas's Cathedral, Bombay, Captain Mark Alleyne Nicholson, I.M.S., to Anne Elizabeth, second daughter of T. Robinson, Esq., The Chestnuts, Danby, Yorkshire.

ROSE—HARRIS.—On Dec. 4th, at All Souls, London, Frank Atcherly Rose, F.R.C.S., of 3 Upper Wimpole Street, to Marian Elizabeth Darling, only daughter of Dr. Alfred C. E. Harris, J.P., of Birkenhead.

Deaths.

ERSKINE.—On Dec. 5th, Ellen Erskine, dearly beloved wife of Robert Erskine, M.D., of 62 Pembroke Villas, W.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX."

Vol. CXLV.

WEDNESDAY, DECEMBER 18, 1912.

No. 25.

NOTES AND COMMENTS.

A Hospital Board with Convictions.

An editorial comment in a lay contemporary alludes to a somewhat new phase in an old standing medical grievance. It states on the strength of a letter from a correspondent that recently a certain London hospital advertised a vacancy for an assistant surgeon. The terms of the appointment prescribed that candidates must be Fellows of the Royal College of Surgeons of England. In the present instance it is stated that at least one gentleman holding that qualification sent in his application, but the Board appointed another candidate who was not thus qualified. Their explanation is that they thought it right to waive the condition of appointment in view of the exceptional attainments and experience of the selected candidate. However that may be, so high-handed a step requires more justification than that contained in the foregoing off-hand statement. The condition, whether good or bad, in itself forms part of the hospital rules and regulations, and having been published in the advertisement for candidates the Board is bound to observe it as a mere matter of good faith and common fairness. The very fact that they have been induced in the present case to break their own law indicates the inherent weakness of the regulation itself, but that does not excuse the Board from the consequences entailed by non-observance of its own deliberate conditions.

"No Scotch or Irish Need Apply."

We have often commented upon the unfairness of the rule that reserves the honorary staff appointments in the large London and in many provincial hospitals for men holding the higher qualifications of the English College of Surgeons and the London College of Physicians. At a single stroke it excludes not only the diplomates of the Scotch and Irish Colleges, but the holders of University degrees in all parts of the Kingdom. Of late years large and flourishing universities have been founded in various parts of England and Wales, and as the number of their medical graduates increases that of the English colleges is likely to fall off in corresponding ratio. Indeed, it may be shrewdly suspected that many provincial men take a higher diploma in London simply with a view of qualifying for a hospital post. It has been said that the multiplication of provincial qualifications will in the course of time solve the difficulty. For all that the unfair restriction in favour of particular colleges must work a great deal of injustice so long as it remains unsettled. Should the Insurance Act bring any measure of State payment to the holders of hospital staff appointments it will necessarily involve the throwing open of such posts to all who hold a legal qualification to practise medicine or surgery. Such

a result would incidentally mean that sooner or later the State would be called upon to consider the question of a one-portal system of medical qualification.

A Matter of Diagnosis.

One of the hardest lessons that the uninitiated have to learn is that medicine is an art rather than an exact science. If this fact were more generally realised much annoyance would often be spared the patient, and the professional actions of medical men would less frequently become the subject of worrying litigation. A case was tried a short time back in Bridlington County Court, in which a charge of negligence was alleged against a well-known medical practitioner for having failed to diagnose an abdominal tumour, the patient's condition being taken by him for pregnancy. The expected event not taking place after the usual period, further advice was sought, resulting in the removal of a tumour weighing over twelve pounds fifteen months after the original diagnosis had been made. The extreme difficulty sometimes encountered in the differential diagnosis of pregnancy and other abdominal conditions is well known, and the very elect have, at times, been quite deceived as to the true state of affairs, even after the most exhaustive examination. The learned deputy-judge was of the opinion that, under the circumstances, no charge of negligence had been substantiated, since a medical man could not do impossible things. It is not always feasible to submit the patient to a radioscopic examination, though, when this can be done, it will often settle the diagnosis one way or the other.

The Unknown Factor in Treatment.

Another medico-legal case of interest to medical men generally, but especially to those who practise electrotherapeutics, is that tried last week at the Birmingham Assizes. The defendants were Dr. J. F. Hall-Edwards and Dr. Emrys Jones, the well-known medical radiographers, the plaintiff bringing an action against them to recover damages for personal injuries sustained through their alleged negligence. The patient, who was suffering from analgesia of the lower extremities and elsewhere, was treated by diathermy, and it was alleged that sparking had occurred, resulting in a form of dermatitis of the leg, from which he was said to have been disabled for nine months. In the evidence of the defendants it was stated that sparking, such as had been described, was impossible with a diathermic apparatus as used by them. Some idiosyncrasy of the tissues of the patient might readily account for the result produced, for it is well known that a person's vulnerability to such injuries is greatly dependent

upon the state of nutrition and nerve-supply of the integument. It is these unknown and unforeseen factors which give rise to many of the inexplicable results in the treatment of disease, in spite of the fact that every precaution has been taken to safeguard the patient. A verdict was returned for the defendants, showing that the element of uncertainty which necessarily pervades the whole of medical treatment is rightly recognised as a powerful factor by those upon whom the responsibility for giving such a decision rests.

LEADING ARTICLES.

THE VERDICT OF THE B.M.A. PLEBISCITE.

THE divisions of the British Medical Association, together with those non-members who accepted the invitation to vote with them, have by a large majority, decided to refuse service under the Insurance Act. In a great number of instances the proportion against acceptance has been five or ten to one, and in some towns, such as Southport, and counties, such as North-East and South-East Essex, it has been unanimous. Some unexpected results have been recorded. In Gateshead, for example, a large majority of medical men voted in favour of acceptance of Mr. Lloyd George's latest terms, whereas they were rejected by the neighbouring practitioners of Newcastle. Birmingham declined the proposals by so narrow a margin that its representative was instructed to vote at the central meeting in accordance with the views of the majority upon that occasion. The Birmingham practitioners in favour of serving under the Act have issued a circular which explains their position. The document is signed by a number of medical men. They estimate that in their town there are more than 500,000 insured persons, the remuneration for attending whom, at 7s. a head, would be £100,000. Of the 400 doctors in Birmingham 300 are in general practice, and if they all served they would have an average annual income of £300 from the insured alone, in addition to their fees from other patients. "Can we," they ask, "afford to reject this?" They further add their opinion that this is the last offer they need expect from the Government. Refusal of the latest terms will be followed by the formation of a whole-time service. They conclude that a number of medical men will be at once available for beginning such an organisation in Birmingham, and that if once formed, the general practitioner will find himself left out in the cold. If the opinion of the majority as recorded in the Association plebiscite is to be maintained, the medical benefits of the Insurance Act will not be available by the middle of January. It is tolerably certain that a certain number of medical men will be found ready to accept service despite the opposition of their fellow practitioners. We doubt, however, if they will be found in sufficient numbers to undertake more than a small part of the service. It may be hoped and believed that the medical profession of the United Kingdom, having arrived at a deliberate majority decision, will loyally abide by that result. On the

Government side an official paper has been issued to all medical men inviting them to accept service under the Act, and to signify their intention before the end of the year, as otherwise, so it is intimated, their names will not be available for service by January 13th, the date on which medical benefit comes into operation. It is difficult to forecast either the issue or the exact methods of the conflict that has now entered into its final stage. The next move must come from the Government. So far as the medical profession is concerned it is not likely to be kept long in suspense as to its chief point of weakness, namely, disloyalty within its own ranks. Apart from this one element of danger, medical men may feel assured of the ultimate success of the fight which has been forced upon them in defence of their plain and legitimate interests.

COMPENSATION FOR SLAUGHTER OF TUBERCULAR CATTLE.

AMONGST the vanishing infections one of the more obstinate is that of tuberculosis. In spite of all scientific advances it exacts a heavy toll from the population of the United Kingdom, and, although an eminently preventable disease, has so far shown small signs of being effectually prevented. The general conclusion from a medical standpoint is that it is possible to cure many cases of local and of pulmonary tuberculosis, but that little can be done in the later stages of the disease. With that experience in view the efforts at prevention, as apart from cure, have received more and more attention at the hands of public health investigators. The later developments of the matter may be said to date from the reports of the British Royal Commission on Tuberculosis, which upset Koch's heresy and demonstrated the identity of human and bovine tuberculosis. From that moment the mind of the scientific investigator became impressed with the supreme importance of dealing with comparative tuberculosis, more especially in those of the lower animals directly or indirectly utilised for the food of man. So far as the infected meat has been concerned, a great deal has been done in recent years to exclude the carcasses of tuberculous animals from our ports, and by stricter and more skilled supervision to weed it out of the home markets. The great source of infection through the milk of tuberculous cows, however, remained practically untreated. It has long been known that by that particular agency of distribution the specific germs of tuberculosis can be conveyed in an active condition, while the undue incidence of tuberculosis upon the infantile population rendered it practically certain that a vast amount of disease originated in the dairy farm and the town dairy. Under such circumstances the step clearly demanded for the reduction of the crusade against tuberculosis to a logical basis was to rid the kingdom of tubercular cattle. Nothing short of that radical procedure could accomplish the desired end of ultimate eradication. The best efforts of the sanitarians were

robbed of their full measure of success so long as an unlimited amount of infection was being constantly spread through the agency of meat and of milk. The main difficulty in the path of any radical reform in this matter lay in the enormous amount of money that would be required to compensate the owners of infected animals. It is with peculiar satisfaction, therefore, that those interested in public health will receive an official announcement from Mr. Runciman, President of the Board of Agriculture, made last week at Whitehall to the National Farmers' Union. He laid down the important proposition that if the slaughter of tubercular cattle took place in the interests of the country as a whole, then the country should be prepared to compensate the farmer for his loss. He had convinced the Treasury, so he said, of the soundness of that view, and he hoped shortly to publish details of a scheme that would redound to the advantage of the community. A large sum of money would be required for the purpose during the first year, but the amount would be a diminishing one in later years. In many ways we regard this as the most important advance that could be undertaken in the fight against tuberculosis. It strikes at the root of the evil and brings us within sight of the disappearance of that scourge into the limbo of extermination that, so far as the United Kingdom is concerned, has happily overtaken plague, cholera and typhus, not to mention others that have been practically ousted. Now that a proper system has been introduced in the sanatorium and home treatment of consumptives, and the general standards of personal and public hygiene raised to a fairly satisfactory level, there is every hope that the last link in the chain of prevention will be supplied by the scheme of compensation for compulsory slaughter foreshadowed by Mr. Runciman.

CURRENT TOPICS.

The Health of the Army in 1911.

THE report of the Director-General of the Army Medical Service upon the health of the troops at home and abroad for 1911 has just been issued. It is highly satisfactory to note that the improvement in the health of the troops is maintained, and that the ratios for admissions to hospital, invalids discharged, and the average number constantly sick are the lowest recorded. The number of recruits brought up for medical inspection was an increase of more than 2,500 over that for 1910, which was partly due to the recent strikes, which influenced recruiting favourably. The better training and instruction of recruiters has led to an improvement as regards the reduction of rejections and early wastage during the past couple of years. The most frequent causes of rejection of recruits in 1911 were diseases of the heart, 41.24 per 1,000; under chest measurement, 30.47 per 1,000; and defective dentition, 26.05 per 1,000. During the past year 1,868 men were invalidated from the service,

659 of whom came from stations abroad, giving a ratio of 8.09 per 1,000, which is the lowest on record. Diseases of the nervous system again give the highest ratio, while tuberculosis and circulatory diseases show a slight decrease on the previous year. Syphilis and digestive disorders show the most pronounced downward curve in the incidence chart. The figures for venereal disease in the army quartered in the United Kingdom are, on the whole, encouraging, and it is to be anticipated that the military inefficiency due to this disease will be further diminished when the combined salvarsan and mercurial treatment becomes universal throughout the army. It has been found that the administration of salvarsan by the intravenous method greatly shortens the time spent in hospital in each case. The ratio of constant sickness per 1,000 of strength was 20.1 in 1911, as compared with 20.4 in 1910, and it is gratifying to observe that these ratios have shown a gradual but steady decrease, year by year. With regard to military hygiene the report states that the consensus of opinion in the various Commands confirms the general impression of improvement in the sanitary administration of the different camps held during the year. Much useful work has been done at the Royal Army Medical College and School of Army Sanitation at Aldershot in connection with field service rations and the supply of a "safe" water to troops in the field. It may be noted that the Army Council has decided to encourage the practice of anti-typhoid inoculation in the army, and with this object explanatory pamphlets in popular language are approved for issue to soldiers on reaching the age when they become eligible for service in the field. In India there is again a considerable decrease in all the ratios, except that for deaths, which gives a very slight increase, chiefly due to cholera and plague. The general improvement reported last year in all the Colonies is likewise well maintained. The report may be considered, therefore, as an eloquent witness to the valuable results that are obtained from the practical application of modern scientific medicine to the daily life and routine of the soldier.

The Medical Acts and the Home Rule Bill

IT is a matter for regret that Mr. Birrell has so completely misunderstood the question of Ireland in regard to the Medical and Dental Acts as to have rejected almost with contempt Sir Philip Magnus' amendment to the Home Rule Bill. Sir Philip Magnus moved a clause intended to prevent the Irish Parliament from dealing with the several Medical and Dental Acts, and to maintain the present powers of the General Medical Council. Mr. Birrell's curt reply was to the effect that the medical profession in Ireland was well able to look after itself, and that it need not be feared that it would act in a retrograde fashion. This argument misses the point altogether. It is not a question of the standard in one part of the three kingdoms being higher or lower than in another. Medical

education in Ireland has long been noted for the high standard maintained. It would, however, be very inconvenient to have separate authorities in the different countries. At present, medical men pass freely from one country to another. If, however, the Irish Parliament were to establish its own Medical Council, with authority over medical education and registration, medical men registered in Ireland might find themselves barred from crossing the Channel. The position would be more than inconvenient, it might easily become intolerable. The Government may be quite right in being unwilling unduly to restrict the powers of the Irish legislature, but if any matters are reserved for the Westminster Parliament, we think that this should be. At the same time, we do not, of course, suppose that an Irish Government is likely to do anything which might injure medical education in Ireland.

The Friendly Societies and the Profession in Dublin.

An important development has taken place in the relations between the friendly societies and the medical profession of Dublin. On October 1st the medical officers of the various friendly societies in Dublin gave notice to their societies that after December 31st they would continue to give their services only on the terms which had been agreed upon by the profession. The time of the expiration of these notices is fast approaching, and many of the friendly societies have recognised the necessity for coming to terms without further delay. As a result, some dozen or more of the friendly societies operating in Dublin—including one of the most important in Ireland—asked last week for an opportunity to put their views before the local Medical Committee. The Committee, therefore, received several deputations last Saturday night. It was gratifying to find that the members of the deputations were unanimous in admitting the obligation the societies were under to their medical officers for their services in the past, and the inadequacy of the remuneration hitherto given. They were willing to offer a distinct advance in the amount of remuneration, though the offer was still behind the demands of the profession. The problem presents many difficulties, but we are sure that personal intercourse, by way of conference between the societies and the profession, is the way by which their solution is most likely to be reached.

The Night Employment of Youths.

An interesting report of the Departmental Committee on the night employment of male young persons in factories and workshops was issued last week as a Parliamentary paper. It is stated that the Committee, though sensible of the fact that night work for boys is both unnatural and undesirable in principle, yet realise that it is essential in necessarily continuous processes in certain industries at the present time, in order to avoid unreasonable loss from waste of fuel or valuable material. Opinions, even of medical men, are apt to differ as to the effects of such employment upon the health of boys, and weighing experi-

ments, carried out by Drs. Bowden and Darcy Ellis, certifying factory surgeons, tend to show that there is little difference between boys who work by day and by night on alternate weeks, and boys who work by day only. An important general conclusion arrived at is that the alternation from day to night work does not always allow sufficient time for the worker to adapt himself to the unnatural conditions. Other objections mentioned are loss of the beneficial effects of sunlight, broken sleep, greater fatigue, irregular meals, less close supervision, and the deprivation of the opportunity of attending evening classes. For these reasons the Committee are strongly of the opinion that the employment of youths under eighteen at night in factories is undesirable. If such employment is inevitable, the employers should see to it that every possible mitigating precaution is adopted.

The New Beit Memorial Fellows.

At a meeting of the trustees of the Beit Memorial Fellowships for Medical Research held last week seven men and two women were elected to Fellowships, six of the former and one of the latter being members of the medical profession. Dr. R. A. Chisholm, who has already undertaken cancer research work, will investigate the production of nephritis by experimental methods and the problems arising therefrom. Dr. D. V. Cow proposes to inquire into the diuretic action of certain tissue extracts, especially that obtained from the intestinal mucous membrane. He will also investigate certain bacterial diseases with the object of ascertaining any possible beneficent action thereon of organic compounds of a non-toxic nature. Dr. A. B. Macallum will study certain problems in metabolism in disease, especially those concerned with the formation of urea and allied compounds. Dr. J. McIntosh, who has already contributed much towards our knowledge of syphilis and its modern treatment, will continue to work at the subject from the point of view of immunity. Dr. S. W. Patterson will investigate the fate of levulose in the normal and diabetic organism, and, later, he will prosecute a research into the toxæmias of intestinal origin, especially the influence of diet on the production of poisonous products. Dr. H. L. H. Schutze proposes to investigate the modern absorption theory of the union between bacillary antigen and the antibodies of the blood serum. Dr. E. J. Dalzell will undertake a research into gastro-enteric diseases in infants. Of the non-medical Fellows, Dr. I. Smedley will continue her investigations into the formation of fat in the organism; Dr. C. Funk will investigate the nature of the so-called deficiency diseases (beri-beri, scurvy, etc.); while Miss H. L. M. Pixell will prosecute a research into the life histories of the parasitic protozoa. The reputation enjoyed by all the new Fellows is such that much useful information may be expected as a result of their individual researches.

Suicide.

AUSTRALIA at present is suffering from an epidemic of suicide, mostly by the methods of drinking lysol, or eating "Rough on Rats." It is a curious fact and one which almost seems to justify the jury's conventional verdict, that a suicide always chooses a handy and fashionable exit regardless of the inconvenience his lack of thought may give him on the way. Few consult their æsthetic sensibilities like Mr. Mantalini. Humanitarians implore the press to refrain from publishing suicide stories, and the press responds by asserting its inalienable right to publish news. Neither side even attempts to controvert the fact that papers convey

the suicidal infection as easily as they do that of scarlatina. The fact is as obvious as it is incomprehensible. We have not yet made up our minds whether suicide is the expression of transcendental heroism or the basest cowardice; probably it is sometimes one, sometimes the other, and often in the same individual we would find it hard to draw the line as long as we continue to class moral and physical courage as different types of the same thing. About the only thing we may be sure suicide is not is temporary insanity. The argument seems to be that no sane man commits suicide, therefore he who commits suicide is not sane, and when he is definitely shown to be of at least normal intellect "temporary" saves us from inevitably stultifying ourselves. The Salvation Army has established a bureau for the prevention of self-destruction, and this institution has been the means of saving the lives of those who while not unwilling to live, despaired of solving the problem of "the concatenation of self-existence."

The Advancement of the Anthropoid Ape.

A COMMITTEE headed by Professor Waldeyer has been formed to establish an institute for the psychological study of the anthropoid. It is estimated that another century will see the extinction of the gorilla, gibbon, chimpanzee, and the other higher apes. Science owes a great debt to these higher monkeys, and she is now determined to squeeze every drop from the simian soul before the last of the great apes walks through the valley of the shadow of death. Somewhere in the Canaries gorillas and chimpanzees are to be collected and studied. It will be an island like that of Dr. Moreau, except that plastic surgery will give way to experimental psychology. Phonation, gesture, comprehension of the spoken word, enumeration, colour perception and educational possibilities are to be studied. Savages who dwell amongst the anthropoids have a universal belief that the latter are not mere brutes, but men like themselves, and the investigators hope to discover mental traits hitherto unknown. The subject is a great and interesting one, but we hope that the education of the ape will not proceed too far. A speaking, sensible and Samsonian gorilla would be a terror in the land, unless indeed he developed like Peacocke's famous Sir Oran. If we are prepared to look upon the anthropoids as men and brothers, we must above all things bear in mind that we are our brothers' keepers.

The National League for Physical Education and Improvement.

THE SEVENTH Annual General Meeting of the National League for Physical Education and Improvement was held at the Mansion House yesterday afternoon as a joint meeting with the Mansion House Council on Health and Housing, the Lord Mayor presiding. With a view of ensuring co-ordination and harmony of action, and to prevent overlapping, the two bodies have now amalgamated. Of even greater importance than this union is the recent federation with the League of the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy. Centralisation and concentration of effort in health matters is powerful for good, and it cannot be too strongly emphasised that the League is always ready to co-operate with other organisations, and is, indeed, anxious to bind together all societies and individuals working for the physical welfare of the nation. The special campaigns organised during the past year, according to the annual report, with regard to the manu-

facture and sale of "safe" flannelette, the physical education summer school, and the health week of 1912, are worthy of the highest sympathy and support of all those who have the physical well-being of the nation at heart. A goodly list of practical pamphlets, written in a terse and popular style, are now published by the League, and these may be specially recommended for wide distribution among the public.

PERSONAL.

DR. J. BRADFORD, of Exeter, has been returned a Conservative member of the Exeter City Council.

DR. DOUGLAS H. FRESHWATER, M.A., M.D., B.C. Cantab., has been appointed Physician to the Western Skin Hospital.

DR. JOHN O'DONNELL has been elected Consulting and Visiting Medical Officer to the Crookslin Sanatorium, co. Dublin.

DR. GEORGE EMERSON BREWER, of New York, has been elected President of the Clinical Congress of Surgeons of North America.

DR. E. RAYNER, of Stockport, has been elected President of the Association of Certifying Factory Surgeons for the ensuing year.

DR. IVY E. HASLAM, M.D., B.S., M.R.C.P.Lond., has been appointed Honorary Pathologist to the Warneford General Hospital, Leamington.

DR. WILLIAM JAMES HOWARTH, M.D., Ch.B.Vict., D.P.H., Medical Officer of the County of Kent, has been appointed Medical Officer of Health of the City of London.

MR. D'ARCY POWER, F.R.C.S., has been nominated to represent the Royal College of Surgeons of England at the International Historical Congress to be held in London during April, 1913.

MR. FREDERICK SYDENHAM, M.D.Edin., F.R.C.S. Edin., D.P.H., has been appointed Honorary Surgeon for Diseases of the Ear, Nose, and Throat at the Warneford General Hospital, Leamington.

DR. T. WINGATE TODD, Lecturer on Anatomy at the Manchester University, has been appointed Henry Wilson Payne Professor of Anatomy in the Medical Department of the Western Reserve University, Cleveland, Ohio.

PROFESSOR ARTHUR KEITH, Conservator of the Museum of the Royal College of Surgeons of England, has been elected Chairman of the Committee which has just been formed for the purpose of organising a museum in connection with the 17th International Congress of Medicine to be held in London next year.

CAPT. R. MARKHAM CARTER, I.M.S., has been appointed by His Excellency the Governor of Bombay in Council to officiate as Resident Surgeon at St. George's Hospital, Bombay, and Professor of Materia Medica and Pharmacy to the Grant Medical College, Bombay, in succession to Capt. R. F. Steele, granted leave of absence.

MR. ROBERT JOHN MONTGOMERY, F.R.C.S.I., M.A., M.B., of Dublin, left personal estate valued at £4,823. The testator left £5,000 to the Board of Dublin University and the Royal College of Surgeons, Ireland, for a "Mary Louisa Montgomery Lectureship" in Ophthalmology, to be held alternately by the said boards for a period of five years, the lectureship for the first five years after his death being held by Dublin University.

A CLINICAL LECTURE

ON

BULBAR AND PSEUDO-BULBAR PARALYSIS.

By F. C. PURSER, M.D., F.R.C.P.I.,

Assistant Physician, Richmond, Whitworth and Hardwicke Hospital.

GENTLEMEN,—I wish to consider with you to-day the condition of two patients who have so many symptoms in common that careless observation would lead you to suppose they were suffering from the same disease. Both patients are men well over 50 years of age, both are unable to sing, whistle, speak, smile, or protrude their tongues, when asked to do so. Both have difficulty in swallowing—especially in swallowing liquids. In appearance they are not unlike, especially in the motionless expression of the lower part of their faces. But the similarity of the two conditions is only superficial, as a little investigation will show. One patient, we are told, has been suffering between two and three years, and during that time he has been getting step by step steadily worse. He has had no other serious ailment. The second patient, who has had other paralytic trouble before this one developed, became affected suddenly about six years ago, and any little change in his condition during those years has been for the better.

Let us examine the former patient first. You see that when asked to put out his tongue he can get it no further forward than his teeth; and you will notice how small the tongue is and how furrowed. His tongue is paralysed, so that he has little or no voluntary power over it to move it in any direction, and, moreover, its musculature is wasted, as its small size shows. The many furrows in its surface are evidence of the extent of the wasting. It shows also fine waves over its surface; these are due to involuntary contractions of little muscle bundles. "Fibrillary twitchings," as they are called, are a sign of progressive wasting, and occur in muscles other than the tongue in states analogous to this.

When he attempts to whistle, for which he has little heart, or to blow out his cheeks, he has no power in the orbicularis oris to purse up his lips, and so his breath puffs out unhindered. His lips, like his tongue, seem thin and wasted, and there is a distinct tendency for the lower lip to droop, which adds to his discomfort, for it allows the saliva to dribble constantly away. When he tries to speak he cannot make himself understood; he cannot produce even a vocal sound. His attempts to do so end in a soft, hoarse guttural. The difficulty in articulation is due, of course, to the condition of his lips and tongue; the aphonia is due to his inability to adduct his vocal cords. Fortunately he has little weakness in the abductors, for that would lead to great narrowing of the glottis during inspiration, and a consequent, perhaps fatal, dyspnoea. Swallowing is also a difficulty. Liquids regurgitate through the nose because the movements of the soft palate are defective, and the nasal cavity is imperfectly shut off from the buccal. He finds it hard to collect dry, solid food into a bolus, and to get the bolus, when collected, back into the pharynx. Once there it goes down readily enough, but often he is unfortunate and a crumb "goes the wrong way." His expulsive efforts, rendered ineffective by his inability to adduct his vocal cords, remove foreign

bodies from the larynx with great difficulty, so that for him this accident is more than an inconvenience; the inhalation of food particles constitutes the very real danger of "aspiration pneumonia." Semi-solid food, like nicely-boiled egg, thick stirabout and jelly, are easiest of ingestion.

These represent the signs of the disease. There are no sensory disturbances whatever; there is no difficulty in biting, the eyelids can be closed tightly; there is no ocular palsy; there is no dyspnoea or alteration in the pulse rate. The symptoms are purely motor symptoms; the motor portion alone of the nervous system is involved. And we can at once limit the site of the lesion to the nerves supplying the affected muscles or their nuclei of origin, for in lesions of the motor tract above the nuclei there is none of the wasting which is so prominent a feature in this patient's muscles. The nerves involved are the 12th especially, and part of the 7th, and the bulbar portion of the spinal accessory, which is now regarded as belonging to the 10th cranial nerve. It is extremely improbable that symptoms so limited have been produced by a neuritis, still more improbable that they are due to multiple lesions affecting symmetrically the affected nerves. The symmetry and the limitation of the symptoms, then, force us to leave a lesion of the nerve trunks out of consideration. We must then locate the disease in the nuclei of the 12th, 7th and 10th cranial nerves, and in view of the slow but progressive course of the disease, we must regard the lesion as degenerative in nature. We are, in fact, dealing with the condition known as labio-glosso-laryngeal paralysis, or progressive bulbar paralysis, in which there is found a degeneration of the cells in the nuclei of the medulla oblongata. The cause of this degeneration is not understood; it is attributed to cold, exposure, worry, over-use—vague enough exciting causes—acting on nerve cells which have an innate tendency to premature degeneration.

The ætiology of the disease being vague, the treatment being of little avail, and the prognosis only too easily guessed, our interest in the condition would seem to be confined to the problem of diagnosis. In a well-developed, typical case, such as this, the condition once seen will not be readily forgotten. The slow, progressive course and the symmetry of the localised wasting without other symptoms or signs occur in no other disease. At its onset, however, it is not so easily recognised. The patient complains of nothing but an indistinctness in speech, especially in words containing t, d, p, b, r, l. This precedes wasting or visible weakness, and may be the first indication of anything wrong. The possibility of the case being one of general paralysis of the insane will occur to you, particularly if the patient give a history of lues: but absence of mental symptoms, pupillary changes, and inequalities in the knee-jerks will help to make the diagnosis. But one may have to wait for wasting to occur to be quite sure, and in the meanwhile urge your patients to try deliberately to speak distinctly; they can often do so unexpectedly

well, no doubt by contracting more forcibly the muscle fibres supplied by cells as yet intact. Occasionally cases are met with where symptoms just like these, including wasting, have come on suddenly—acute bulbar paralysis. These are dependent on vascular changes, usually thrombosis, in the little vessels supplying the medulla. But they are usually more random in their distribution than the degenerative lesion, and when not fatal at the outset they tend to lessen in severity rather than to increase.

I need not point out the similarity between this disease and the much commoner progressive muscular atrophy, which is due to degeneration in the cells in the anterior horns of the spinal cord. There is no doubt the diseases are one and the same—it is a matter of the location of the degeneration whether the disease is "bulbar paralysis" or "progressive muscular atrophy" of spinal origin. Bulbar paralysis frequently supervenes on a progressive muscular atrophy, and wasting in the limbs is not infrequently observed after bulbar symptoms have been well established. And just as with progressive muscular atrophy, we often get a spastic condition of the limbs with increased tendon reflexes, and dorsiflexion of the toes on stroking the soles, so in bulbar paralysis we may find similar phenomena in the limbs. This is worth remembering lest its discovery may cause a doubt in the diagnosis.

There is a point of great interest, pointed out by Gowers, which is well illustrated by this case—namely the tendency of the degenerative process to affect parts in close functional relation to each other apart from any anatomical contiguity. Thus we see that with paralysis of the tongue there is a paralysis also of the lower part of the face. But the orbicularis palpebrarum and frontalis muscles, which also are supplied by the facial, are unaffected. When, as sometimes happens, the ocular nuclei are attacked by the degeneration the 3rd nerve nucleus and the 6th, and even the upper part of the 7th, suffer together. These nuclei have a close functional relation to each other, though anatomically they are far apart—much further apart than the 12th and 7th nuclei. What the exact connection between the 12th and 7th nuclei is is not determined, but that it is very close you can easily prove for yourselves. If you try to protrude your tongue flat you can do so only by making the orifice of your mouth as wide as possible, and no effort to narrow your tongue by contracting its transverse fibres will be successful unless you at the same time narrow the orifice of your mouth.

Bulbar paralysis has so far proved beyond remedy. Treatment must be symptomatic. Avoid what may add to the danger, such as exposure, which may lead to laryngitis and bronchitis. Strychnine hypodermically, phosphorus and arsenic may be tried, but at best they only stay the rapidity of the degeneration. In cases which give a syphilitic history mercury, iodides, and salvarsan should be given.

Now let us examine our other patient. He, too, has imperfect voluntary control over the muscles of his lips and tongue. He has rather more control over his larynx, and his palate moves fairly well now. He has less power in the masseters, and he cannot move his jaw at all from side to side. But the essential difference between the two cases is that in this instance there is no wasting to speak of, and no fibrillary twitching, which are such prominent features in the first case. This is because the lesions which have given rise to his condition are situated above the nuclei which directly innervate and preside over the nutrition of the affected muscles.

The history of this patient is very interesting, and as he has been under observation ever since he first got ill it is fairly trustworthy. He is a right-handed man. Eight years ago he got a slight right-sided hemiplegia when out walking. It was attended with no loss of consciousness and no convulsions, and he was able to walk slowly home. The weakness was extremely slight; there was little dysarthria, no aphasia. Some months later he got another attack on the same side, and yet a third attack—both extremely slight. The dysarthria and residual right-sided weakness were really inconsiderable. About six years ago, while sitting quietly reading, the patient suffered from a momentary loss of consciousness, followed by weakness in the left arm and leg. Considerable difficulty in swallowing followed immediately, saliva dribbled profusely and unchecked from his mouth. His speech an hour later was hardly intelligible, and in two days had become quite unintelligible. To make a long story short, he recovered a fair amount of power in his lips and in swallowing, and the arm and leg also improved. But his power of speaking has not returned in all these years. Mentally he is very bright, and is able to follow his sedentary occupation efficiently.

The explanation of this sequence of events I suppose to be this. There have been a succession of thromboses in small vessels in the brain. The first three were in the left hemisphere. They were not in the cortex, but somewhere in the pyramidal tract, where the fibres are close together—quite likely at the genu of the internal capsule. They were not in the cortex, because if there to give rise to such widespread symptoms the area affected would have been necessarily large, and aphasia would probably have resulted also. The trifling involvement of the face and tongue and the sparing of the larynx and palate were due to the fact that their muscles on each side have a double cortical innervation. The muscles supplied by cranial nerves on one side are innervated principally from the opposite side of the brain, but also very largely from the same side of the brain. Hence paralytic symptoms, even when the principal innervation path is destroyed, are slight in these regions as compared with the paralysis of the limbs, and when they occur they tend to disappear comparatively rapidly. This is most especially true as regards the vagus, but it holds, though less completely, for the other cranial nerves also. The final attack was of rather greater severity than the others. It was due to a lesion in the right cerebral hemisphere in a position probably similar to those in the left hemisphere. By cutting off the innervation from the right cortex it has given rise to the affection of the cranial nerves which we have just examined.

There is one further point to which I wish to direct your attention. The patient, despite his handicap, seems a very hilarious person. A trivial pleasantry leads to an outburst of merriment quite too flattering to its deserts—and when the patient laughs his whole face is contorted with glee. The muscles we have been looking on as partially paralysed appear suddenly to have acquired a power of contracting greater than we expect in health. This is due to the uncontrolled action of some subcortical centre on the bulbar nuclei. In the beautiful simplicity of upper and lower motor neurone symptoms, which forms the A.B.C. of diagnosis of diseases of the nervous system, we are apt to forget that tracts other than the pyramidal tracts also act on the lowest nuclei. Probably, though not absolutely certainly, the optic thalamus is the centre wherein arise the outward expressions of emotion. It acts under the control of the cortex as a rule.

In this case, probably, it acts unrestrained—the cortico-thalamic fibres having been involved in the softenings. The reverse occasionally is met with—the patient smiles perhaps only with one side of his face when he is genuinely amused, but when he comes to smile voluntarily there is nothing to choose between the two sides. This patient may go on as he is for many years, but it is unlikely now, six years from his last stroke, that he will get any better.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by H. E. Symes-Thompson, M.A., M.D. Cantab., M.R.C.P. Lond., Assistant Physician to the Royal Hospital for Diseases of the Chest. Subject: "The Selection of Cases of Pulmonary Tuberculosis for Institutional, Domiciliary and Dispensary Treatment under the National Insurance Act."

ORIGINAL PAPERS.

THE NEUROLOGY OF THE VISUAL SYSTEM.

A Short Series of Original Papers.

By HARRY CAMPBELL, M.D., F.R.C.P.,

Physician to the West End Hospital for Diseases of the Nervous System.

PAPER V.

THE INTRINSIC MUSCLES OF THE GLOBES.

Nerve supply.—The globe and its intrinsic muscles are supplied by the two long ciliary nerves from the nasal, and six to twelve short ciliary nerves from the ciliary ganglion. This consists of a small reddish mass situated between the optic nerve and the external rectus (see fig. 29.) It receives a

FIG. 29.—Diagram of the ciliary ganglion and the ciliary nerves. The ganglion is seen to spring from three roots—one from the nasal, one from the sympathetic, and one from the third nerve. It gives off six to twelve short ciliary nerves. The nasal gives off two long ciliary nerves. The ciliary nerves, long and short, pierce the sclerotic near the entrance of the optic nerve, and course forward between this and the choroid, as represented by the interrupted lines.

sensory branch from the nasal division of the ophthalmic nerve, a motor (autonomic) branch from the inferior division of the third nerve, and a branch from the cervical sympathetic.

The long ciliary nerves are sensory. The short ciliary nerves contain: sensory fibres (through the sensory nasal root); motor fibres to the irido-constrictor and ciliary muscle (through the autonomic fibres contained in the third nerve); motor fibres to the irido-dilator, and vaso-motor fibres (through the cervico-sympathetic which issues from the cord with the first pair of thoracic roots). The irido-dilator and vaso-motor fibres leave the sympathetic trunk at the base of the brain, join the Gasserian ganglion and are conveyed to the ciliary ganglion through the nasal division of the ophthalmic; or they may come off directly from the cavernous or carotid plexus. Other irido-dilator fibres are said to be derived from the brain-

stem through the fifth nerve, passing to the iris through its nasal branch.

The ciliary nerves, long and short, pierce the sclerotic near the optic nerve and course forward between this coat and the choroid. They supply the globe with sensory, motor (to the irido-dilator, the irido-constrictor, and the ciliary muscle), and vaso-motor fibres. The ciliary nerves form a gangliated plexus among the blood-vessels of the choroid, and a similar plexus in the ciliary muscle and the iris.

Regarding the origin of the autonomic (pre-ganglionic) fibres of the third nerve, it was until recently thought that they all came from the anterior part of the third nerve nucleus, which contains smaller cells than the posterior portion. There is, however, little doubt that the nerve-fibres subserving the light reflex (effected through the irido-constrictor), if not those pertaining to accommodation (effected through the ciliary muscle and the irido-constrictor), come direct from the superior colliculus (figs. 24, 25, 30.) The latter receiving, as

FIG. 30.—The fine retinal fibres in the optic tract can be seen terminating in the corpus genic. ext. and the pulvinar, in which structures a further set of cortico-petal visual fibres arises. The coarser light reflex fibres (a and a') terminate either in the superior colliculus, whence a further set of neurons pass directly into the third nerve, or they terminate in the nucleus of the third nerve.

it does, fibres both from the retina and the visual cortex, can be stimulated from either of these regions. It is also connected with the cervical spinal cord through the tecto-spinal tract, which runs down the tegmentum of the pons and medulla and in the antero-lateral column (fig. 31), to terminate in the ventral horns of the cord.

THE PUPILS.

In complete relaxation of the iris (e.g., after division of the short ciliary nerves) the pupil is considerably, but not completely, dilated (paralytic mydriasis). If cocaine be applied to such a pupil, further dilation is effected by stimulation of the sympathetic, which causes the dilator fibres to contract (spastic mydriasis). Hence the pupils can be made to dilate, either by inhibition of third nerve activity, or by augmentation of sympathetic activity. Contrariwise, they can be made to contract, either by stimulation of the third nerve (spastic myosis) or inhibition of the sympathetic (paralytic myosis). The action of the third nerve on the irido-constrictor plays the more important part in regulating the size of the pupil.

The fibres of the short ciliary nerves supplying the iris break up within this structure into a plexus containing numerous ganglion cells, endowed with some measure of autonomic control over its musculature. The ciliary ganglion also exercises some control over the muscles of the iris. Thus, Fr.

Frank has shown that while section of the third nerve fibres before their entrance into the ganglion causes incomplete mydriasis, section of the fibres issuing from the ganglion (in the short ciliary nerves) causes complete mydriasis, proving that the ciliary ganglion continues to maintain some tonic contraction of the irido-constrictor after section of the third nerve. Again, stimulation of the short ciliary nerves causes a greater contraction of the pupil than does stimulation of the third nerve.

The action of drugs on the pupil is typified by atropine, eserine, and cocaine. Atropine paralyses, while eserine stimulates, the motor terminals of the sphincter. Cocaine excites the motor terminals of the dilator.

Paralytic mydriasis (paralysis of the third).—The pupil is unaffected by light, accommodation, or convergence. It can be made to dilate through the sympathetic. Atropine, by paralysing the terminals of the third nerve within the sphincter, increases the dilatation; eserine, which stimulates these terminals, causes the pupil to contract; cocaine, which stimulates the nerve terminals of the irido-dilator, increases the dilatation.

Spastic mydriasis (stimulation of the sympathetic).—The pupil contracts in response to light, accommodation, and convergence, although, perhaps, less readily than normally. It fails to dilate further through the action of the sympathetic, e.g., from emotion, cutaneous stimulation, or the application of cocaine. Atropine, on the other hand, increases the dilatation to the maximum by paralysing the antagonising sphincter and allowing the dilator undisputed sway.

Spastic miosis (stimulation of the third nerve).—If the miosis is not maximal, further contraction results from the action of light, accommodation, and convergence. Atropine causes dilatation by paralysing the sphincter. The stimulating action of cocaine on the irido-dilator has no effect on the spasm of the constrictor.

Paralytic miosis (paralysis of the sympathetic).—The pupil, which is only slightly narrowed, does not dilate in response to sensory stimulation of the skin, or psychic influences. It contracts to light, accommodation, and convergence. Atropine causes a moderate dilatation, the ample dilatation of the pupil produced in the normal eye by this drug being due to the action of the dilator unopposed by the sphincter. Cocaine causes dilatation, if the sympathetic terminals in the dilator remain intact. Eserine produces a maximal myosis by inducing spasm of the sphincter.

Normal Variations in the Size of the Pupil.—The size of the pupil varies normally under the following conditions:—

1. Examination of the pupil in a bright light with a magnifying lens shows that it is normally never stationary, but undergoes rapid contractions and dilatations, varying both in rate and amplitude. Loss of this "pupillary unrest" indicates disease. Such loss may precede the occurrence of the Argyll Robertson pupil. This condition is distinct from "hippus," which is pathological.

2. The pupils vary in response to the action of light. Light falling upon the retina causes the pupil to narrow; the shutting out of light causes it to dilate. These effects constitute the light reflex. When light is allowed to fall upon one eye the pupils of both eyes contract, that of the shaded eye the less of the two (the consensual light reflex). Similarly, when one eye is shaded both pupils dilate, the unshaded pupil the less of the two. (An electrical instrument has been constructed which enables light to be thrown suddenly into one eye to the exclusion of the other.) Under

bright light (e.g., sunlight) the pupils contract to a pin-point; in complete darkness they tend to dilate fully. The effect of darkness in causing the pupil to dilate is well seen in senile miosis. Though small in bright daylight, the pupils, as evening comes on, dilate. In order to test a pupil which reacts sluggishly to light, the patient should be taken into a dark room and artificial light concentrated upon the pupil by means of a lens. Most pupillary reactions are best tested in a sombre light.

The Light Reflex Arcs.—As to the first and last of the links in this arc, there is no doubt. The initial link is composed of the retinal cones, which, through the mediation of the "bipolars," are placed in relation with certain of the "ganglionic" cells. These give origin to fibres, coarser than the visual fibres, which run in the optic nerves. The final link is formed by the short ciliary nerves coming off from the ciliary ganglion. As to the intermediate link, or links, opinion is still divided.

The Short Arc.—Bernheimer maintains that the retinal fibres, having traversed the optic tract and the white substance of the superior colliculus, pass directly, or after decussation, into the anterior part of the third nerve nucleus, where there arises a further set of neurons sending their axons into the ciliary ganglion. (Fig. 30.)

Bach, however, claims to have shown that the optic nerve fibres subserving the light reflex terminate in the lateral part of the superior colliculus, and that the axons, for the most part decussating, of a further series of neurons pass direct from this structure through the third nerve to the ciliary ganglion without touching the third nerve nucleus. (Figs. 24, 25, 30.)

The Long Arc.—In addition to this short arc there is also, according to this observer, a long light reflex arc; the fibres descend from the external part of the superior colliculus (Fig. 32) to an inhibitory centre in the medulla at the lower level of the calamus scriptorius; from this centre a further set of decussating fibres ascend by the posterior longitudinal bundle, either directly to the third nerve and thence to the ciliary ganglion, or to the third nerve nucleus, whence a further set passes to the ciliary ganglion.

The coarse "light reflex" fibres passing from the retina behave, as regards decussation, like the fine "visual" fibres—i.e., those from the nasal half of each retina decussate in the chiasma, while those from the temporal halves pass direct into the corresponding optic tracts (Fig. 30). Hence hemianopia, due to lesions in the optic chiasma or optic tracts, shows loss of light reflex on the blind halves of the retina. Such loss indicates that the lesion is either in the chiasma or one of the optic tracts (Wernicke's sign). In testing for the hemiopic reaction the difficulty is to confine a pencil of light to the blind portion of the retina. For this purpose a special instrument has been devised. If the light reaches the macular region the pupil necessarily contracts. This region is the most sensitive to the light reflex; thence outwards the sensibility of the retina to the light reflex diminishes.

3. Accommodation consists of a varying contraction of the ciliary muscle leading to a corresponding modification in the convexity of the lens. This lenticular change is attended by an associated modification in the convergence of the eyes and in the size of the pupils. Thus, in directing the gaze from a distant to a near object three things happen: the ciliary muscles contract allowing the lenses to bulge, the axes of the eyes are converged upon the object fixed, and the pupils narrow. Each of these actions is controlled by a separate nervous mechanism, which may be separately disturbed.

They are all, however, under the control of a higher centre which secures their co-ordinated activity. Although contraction of the ciliary muscle is normally attended by a narrowing of the pupil, this is not always the case. Thus, in the spasm of accommodation which so frequently occurs in young people there is no corresponding contraction of the pupil. The act of converging the optic axes appears to be more intimately associated with the contraction of the pupils than the act of accommodation. Thus during voluntary convergent squint the pupils may be observed to contract. Some, therefore, regard this "convergence contraction" as distinct from accommodation contraction. In either case the pupillary contraction must be regarded as an associated contraction rather than as a reflex action.

Accommodation contraction is greater than that produced by the light reflex, unless the light is very bright: even the pin-point pupil of tabes contracts on accommodation.

We are even more in the dark as to the nervous mechanism of accommodation contraction of the pupil than we are as to that of the light reflex. All we can say is, that the autonomic fibres subserving the contraction of the pupil and the ciliary muscle in accommodation run in the third nerve to the ciliary ganglion, and thence by the short ciliary nerves to the globe. It has generally been assumed that the autonomic fibres in the third nerve, controlling both the contraction of the ciliary muscle and of the iris in accommodation, arise in the anterior part of the third nerve nucleus.

Stimulation of the third nerve causes a contraction of the pupil and of the ciliary muscle—*i.e.*, it increases accommodation. According to Morat and Doyon, stimulation of the sympathetic has the opposite effect, not only on the pupil, as is well known, but also on the ciliary muscle.

4. During sleep the pupils undergo extreme contraction, while the cornea moves upwards and inwards.

5. On firmly closing the eyes (as happens when a strong light falls upon them, or on the sudden approach of an object), the pupils contract and roll upwards and inwards. This is a protective reaction. It should be tested in a dull light.

6. The pupils tend to widen on painful stimulation of the skin, especially when the stimulation is made in the cervical region. The dilatation takes place slowly, and sometimes to a considerable degree. It is caused by a reflex stimulation, through the sensory nerves of the skin and the cervical sympathetic, of the irido-dilator. This test is also best made in a dull light.

7. The pupils may alter in size in response to stimuli proceeding from the cerebral cortex: they contract in voluntary convergence and in concentrated attention; they dilate in strong emotion, or as the result of loud noises. It is said that the mere thinking of a bright or a dark object may cause the pupils to contract or dilate. A Hungarian physician is asserted to have been able to dilate his pupils voluntarily.

8. Certain non-visual peripheral reflexes of the pupil are described as taking place through the ciliary ganglion. Such are the pupillary changes resulting from the local action of heat, cold, and electricity. The "orbicularis phenomenon" possibly belongs to this class.

(To be continued.)

THE PRESENT POSITION AND PROSPECTS OF MEDICAL PRACTICE. (a)

By SIR HECTOR C. CAMERON, F.R.F.P.S., LL.D.,

Emeritus Professor of Surgery, University of Glasgow.

* * * * *

You are setting out, gentlemen, at a point of time in the history of the healing art full of good auspices and big with the promise of progress, because its work is now more and more becoming based upon sure and stable foundations. If I contrast its present position and prospects with those it possessed when I became a student of medicine in the early sixties, language can hardly exaggerate the difference. At that time such boast of comparatively recent progress as existed centred around the use of the stethoscope and anaesthetics, but general blood-letting was not yet wholly abandoned, while the use of leeches and other means of abstracting blood locally was a daily routine. Pathology, as a science, was only beginning to be cultivated, and, except in the University of Edinburgh, I question whether in Great Britain there was a professorship or lectureship, and certainly there was no equipped laboratory, established for its teaching. No separate instruction on the subject was given at all in my own University—that of Glasgow—except such teaching as was connected with the making of *post-mortem* examinations and with the demonstration of the gross evidences of disease to be found in different parts of the dead body. The microscope was in the hands of experts, but few students were trained in its use. Then, and for many years to come, the methods of diagnosis, of differentiation between hitherto apparently similar states of ill-health, as well as the means of successfully treating and preventing many formidable and most fatal diseases, which have of late years flowed in so full a flood from the still very young science of bacteriology were, as a matter of course, unknown and undreamt of. The only guides for the physician and surgeon in charge of acute and dangerous illness were the pulse rate, the state of the tongue, and the general aspect and behaviour of the patient, for even the clinical thermometer and the temperature chart were not yet devised. That pedantic word *gynaecology* was still uninvented, and the diseases of women were dealt with almost entirely by the physician with the aid of the drugs of the pharmacopœia. Typhoid was only beginning to be generally differentiated from typhus fever; both were abundant in all large centres of population, and the latter claimed among its victims great numbers of medical practitioners and students, for the subject of Public Health was in its infancy and was neither known, practised nor taught, as we now understand it. Every wound, whether accidental or made by the surgeon, with extremely few exceptions, discharged pus freely; and putrefactive changes occurring in all of them, produced in the atmosphere of every surgical ward, no matter how spacious and well-ventilated, a fœtid sickening odour which tried the student on his first introduction to surgical work more even than the unaccustomed sights of the operating theatre. In every surgical clinique Death held perpetual court, for wound-begotten diseases—hospital gangrene, pyæmia, tetanus, and the rest of that fatal brood, which, thank God, are now to all intents and purposes banished from surgical practice—were never entirely absent, at any time, from the hospitals of that day. No matter how carefully and skilfully an operation was performed, the issue was looked forward to with anxiety and dread. Few of those who did recover did so without serious episodes in their illnesses and disquieting complications of some sort. All suffered from pain and fever, more or less severe, and convalescence was only reached after weeks or months of distressing experiences of many kinds. I have myself, when a student, seen no fewer than five patients suffering from pyæmia which followed amputation for injury, die in the course of one week in a single ward of twenty beds, while other instances of the same disease and of hospital gangrene lay around them. Probably few of

(a) Abstract of Opening Address delivered at the Faculty of Medicine, University of Toronto, October 4th, 1912.

The First Lady L.D.S.Eng.

At a meeting of the Council of the Royal College of Surgeons of England, held on December 12th, Miss Lily Fanny Pain, of the Royal Free and National Dental Hospitals, was admitted the first lady Licentiate of the Royal College.

you may see more than five amputations of injured limbs during all your studentship—so great has been the progress of conservative surgery—and those which you do see, if only the patients survive the shock of their original injuries, will probably all recover.

For our complete emancipation from the dreadful evils of those dark days of surgery and for no small part of the remarkable advance made also in the domain of the physician, we are indebted to the life and work of that great man, Lord Lister, who died only last February, and whose career has since been commemorated as the boast and the blessing of our profession in every civilised land and nowhere more heartily and warmly than in this city of Toronto. Great in character, as well as in achievement, he will ever remain an exemplar for all of us; and I feel inclined to suggest to you one or two lessons—we have no time for more—to be derived from facts in his life, lessons which may have special interest for you now and may be of value hereafter. And first, I should like to recall and relate to you a little chapter of medical history, which concerns him and must always be of interest to every teacher and student of clinical medicine, surgery and midwifery.

I have indicated to you the awful mortality which occurred in surgical hospitals at the time of which I have been speaking. Equally appalling was that to be met with in all maternity charities. At least one other than Lister was working actively and earnestly, although in a very different direction, with a view, if possible, of furnishing a remedy. I refer to the late Sir James Simpson, the celebrated Professor of Obstetrics in the University of Edinburgh.

He had been long struck by the great maternal mortality then prevalent among the patients of lying-in hospitals, as compared with that which obtained in the case of women delivered in their own homes; and knowing how analogous were the circumstances of the newly-emptied uterus with that of the newly-inflicted wound, and how similar were the dangerous and often fatal sequelæ of each, he was prepared to find a like disproportion between the number of deaths of those operated on in private practice and those treated in what he spoke of as "palatial hospitals." It was the unfavourable environment, therefore, of the patient which he regarded as the real cause of disaster, and it was the practice of collecting together many wounded persons under one roof which he set himself, with all his accustomed energy, to denounce and, if possible, to alter and supersede. He wrote and spoke on the subject with the frequency and force of an earnest agitator, so that much attention was aroused by his views and not a few influential converts adopted his creed. In a pamphlet entitled "On Our Existing System of Hospitalism and Its Effects," he wrote as follows:

"Above twenty years ago, in speaking of the effects and evils of our large hospitals—as these hospitals are at present constructed—I took occasion to remark: 'There are few or no circumstances which would contribute more to save surgical and obstetric patients from phlebotic and other analogous disorders than a total change in the present system of hospital practice. I have often stated and taught that if our present medical, surgical, and obstetric hospitals were changed from being crowded palaces—with a layer of sick in each flat—into villages of cottages with one or, at most, two patients in each room, a great saving of human life would be effected; and if the village were constructed of iron—as is sometimes done for other purposes—instead of brick or stone, it could be taken down and rebuilt every few years—a matter, apparently, of much moment in hospital hygiene.' Since the date mentioned," he continued, "I have conversed on many occasions with many medical men on this subject. I have found, however, that to most professional men it seemed to be altogether a kind of medical heresy to doubt that our numerous and splendid hospitals for the sick poor could by any possibility be aught than institutions as beneficial in their practical results as they were benevolent in their practical objects. When acting in 1867 at Belfast as President of the Public Health Section of the National Association for the Promotion of Social Science, I spoke

on the subject of Hospitalism at some length in my Inaugural Address, and propounded the questions—to what extent are hospitals, as at present constructed, banes and blessings? and, how can they be changed so as to convert them from the former to the latter? I conclude my remarks on this point by again suggesting publicly that to render our hospitals as healthy and useful as possible, and in order to acquire sufficient space and air and isolation for their sick inmates, they should be changed from wards into rooms, from stately mansions into simple cottages, from stone and marble palaces into wooden, or brick and iron cottages. On the same occasion, after speaking of the relative treatment of some diseases such as fevers, etc., in and out of hospitals, and after showing—chiefly from the large statistics of Mons. Lefort—that as a general rule, parturient women recovered in a much larger proportion when delivered in their own homes than when delivered in lying-in hospitals, I proceeded to ask: 'In regard to surgical patients in hospitals, does the same law hold good as in respect to obstetric patients? At the present time medical science is, I believe, in want of any sufficient data to determine the question. The general mortality in hospitals after operations is confessedly very great, far greater than was believed a quarter or half a century ago, when no sufficient statistics had been collected on the matter. The man laid on an operating table in one of our surgical hospitals is exposed to more chances of death than the English soldier on the field of Waterloo. Some authors have collected on a large scale the statistical results of some operations and particularly of amputations of the limbs. Out of 1,656 cases of amputation performed in the hospitals of Paris and collected by Messieurs Malgaigne and Trelat, 803 died, or nearly one in every two. Dr. Fenwick has collected together from various sources 4,937 cases of amputations of the limbs. Of these, 1,562 died, or nearly one in every three or four. "The assertion," observes Dr. Fenwick, "that one person out of every three who suffers an amputation perishes would have been repudiated a few years ago as a libel upon the profession, and yet such is the rate of mortality observed in nearly 5,000 cases." Are the results of amputation," in conclusion asked Sir James Simpson, "in dispensary, private or country practice as deplorable? Adequate data have not been collected. Certainly the general belief of the profession is that in country practice amputations are not so frightfully fatal."

In order to settle this point, if possible, he collected extensive statistics of the results of amputation in rural practice. These he obtained by addressing a circular letter, with an accompanying schedule to a great number of medical men practising in the provincial and rural parts of England and Scotland, requesting them to furnish him with the results of the limb amputations which had been performed by them in their private practice. The returns obtained from these applications numbered altogether 2,098 cases of amputation. The total number of deaths was 226, *i.e.*, one in every 9.2 died or 10.8 in every 100. He compared with this mortality that of a similar number of limb amputations performed in the Royal Infirmarys of Edinburgh and Glasgow, and in nine of the leading London hospitals. In these 2,089 limb amputations performed in eleven great hospitals by surgeons of skill and experience he found that no fewer than 855 had died, *i.e.*, 1 in 2.4. In other words, almost one half of the patients operated on died. Simpson concludes his pamphlet thus:—

"This excess in about 2,100 limb amputations, of 620 deaths in hospital practice as compared with our rural villages and cottages; in large wards as compared with isolated rooms, is certainly much greater and more pronounced than I myself expected when I began the present inquiry. But must the calling of this dismal death-roll go on unchallenged and unchecked? Shall this pitiless and deliberate sacrifice of human life to conditions which are more or less preventable be continued or arrested? Do not these terrible figures plead eloquently and clamantly for a revision and reform of our existing hospital system?"

The pamphlet from which I have thus freely quoted

was published and scattered in great profusion and in all directions in the spring of 1869, and if it did not succeed in bringing about the reform of hospitals which its author desired, it was not because he died only a year after its publication. There were many ardent disciples who would gladly have carried on the propaganda. But happily, the difficulty was to be solved in a very different way. Just after leaving Glasgow in 1869, and only a few months before Simpson died, Lister published a paper entitled "On the Effects of the Antiseptic System of Treatment upon the Salubrity of a Surgical Hospital." His first experience as a hospital surgeon began in the Royal Infirmary of Glasgow, at that time one of the most unhealthy of hospitals; but, ere he left it, the effects of his new treatment on the health of the wards was manifest to all who witnessed them. As he himself declared, that treatment was in the highest degree beneficial, converting the wards from some of the most unhealthy in the kingdom into models of healthiness.

How amply his anticipations have been fulfilled is probably known to all of you. The very word "hospitalism" died an early death and has entirely dropped out of medical literature. Our splendid opportunities of successfully prosecuting clinical practice, research and instruction have by Lister's discoveries been more than fully preserved to us. It requires no great power of imagination to realise how entirely they would have been destroyed and lost by any scheme which scattered our patients over many roods of ground and housed them in camps or villages of two-roomed cottages. Instead, fortunately, they are still accommodated and compactly housed in flats even more numerous than Sir James Simpson ever saw, and with even larger "layers of sick" on every floor. No outcome of the antiseptic system of treating wounds occasioned Lister more pleasure and pride than this one. The Royal Infirmary of Glasgow, in which he had such unhappy surgical experiences when he joined its staff in 1861 has yielded almost from the time he left it until its recent reconstruction, although composed of the same walls and floors as in his day, as good results as any other hospital in existence. He himself had always practised in very old hospitals and operated in theatres of old-fashioned construction, but he knew that he could depend on securing the best results in his wounds; and so he proved the fact that it was not necessarily change in the environment of the patients, but the avoidance of sepsis in their wounds, which was required to ensure salubrity and a low death-rate in surgical hospitals. To that discovery you owe the continuance of your splendid and convenient opportunity of clinical study. You owe also a sense of gratitude to the memory of the man who made the discovery in the face of much hostile and often bitter criticism and at a most serious crisis in the history of hospital administration and construction.

In the introductory address which Lister delivered to the students of Edinburgh on "The Causation of Putrefaction and Fermentation," when he entered there upon his duties as Professor of Clinical Surgery, in the winter of 1869, he concluded in the same strain of confidence to their ability to draw just conclusions in matters of fact. "I commend these facts," he said, "to your candid and impartial judgment, beseeching you to form your own opinion regarding them. The minds which you bring to bear on this subject to-day are very much the same as they will be throughout your lives. An observation which any one of you may make now will serve, in after life, to illustrate a course of lectures, should he occupy a position corresponding to that which I have now the honour to hold. And you are as competent as you ever will be to draw logical conclusions from established data. Do not let any authority shake your confidence in knowledge so obtained."

But it is a struggle in which something more is needed for success than accurate knowledge and wise skill. The practitioner must recognise that a high moral standard of conduct is required of him. It is difficult to convey, in a few sentences, what such a

standard should be. I once made the attempt to indicate this to an audience much the same as that which I have now the honour to address and, perhaps, I cannot do better than repeat to you the words I then used. "The practitioner of medicine," I said on that occasion, "however ably he cultivates both its science and art, will fall far short of its highest ideal unless he also tries to illustrate, in his daily round, what one may call, for want of a better term, the moral side of his profession. To devote himself to a daily and often self-denying personal service of the sick; to render that service truthfully, soberly and chastely; to resist all temptations to self-advertisement and the depreciation of rivals—for the depreciation of others is only another form of self-approbation; to be silent in regard to much of what he sees and is told in the houses into which he enters; to be chivalrously regardful of the modesty of women, sympathetic with the easily-aroused fears of little children, and patient with all manner of men; to feel on many an occasion much more anxiety than he shows; not to be untruthful to the sufferer from hopeless disease, and yet to remember, as Sir Thomas Browne, himself a physician, has said, that 'it is the heaviest stone that Melancholy can throw at a man to tell him that he is at the end of his being'—these, and many other difficult duties and acts of self-discipline like these, are incumbent upon every medical practitioner."

Gentlemen, the ideal of conduct such as I here endeavour to indicate is far from being easy of attainment, and there are few of us, perhaps, who completely and adequately fulfill its requirements. But all its essentials may be learned and practised even during your student life. The formation of your character is in process as surely as is your acquisition of knowledge, and in wishing you all success in your work here and hereafter, I conclude by impressing upon you that he who faithfully pursues his studies now, who gradually acquires skill by the fusion of his knowledge with his growing experience and who guides all by a high ethical standard in respect both of his patients and of his professional brethren is the man who, in the struggle of the coming years, will be found amidst the sunshine and hope of the van and not amidst the dust and fatigue of the rear.

THE TRIUMPH OF QUACKERY.

By HENRY SEWILL, M.R.C.S.

A YEAR or so ago I expressed the opinion that the case for medical law reform was overwhelming, and needed only to be stated in an unimpeachable fashion to render certain the attention and intervention of Parliament. I had for a long time urged continually that the case could be set out in the desired manner in one way alone, namely, through the medium of a Royal Commission, charged to report not only upon unqualified practice, but upon the traffic in quack medicines and appliances—a traffic which has always formed the cloak for a vast amount of illegal practice. I now repeat the deliberate opinion which I quite recently put forth, and about which I am asked by one of your correspondents for further information—namely, that the prospects of medical law reform are for the present completely destroyed.

My changed attitude has been brought about by events during the past two or three years. During this time it has been shown that there exists a considerable section of the profession that upholds quackery, both in the form of practice by unqualified pretenders and the sale of quack medicines. It has been proved that qualified men can always be found to take positions as partners, assistants and supporters of quacks, however fantastic their claims, and that many of these men before the Medical Council and in the law courts are ready to testify to their belief in the *bonâ fides* of their associates, and in the efficacy of their methods and remedies.

Some of these men are no doubt fully alive to the character of the enterprises to which they lend themselves. This is from time to time clearly brought out before the General Medical Council, when the names of offenders are struck off the Register for "infamous

conduct in a professional respect." This penalty has, however, no terrors for these men. They can go on practising as before, and can still assume the titles of which they have nominally been deprived. On the other hand, it is certain that many practitioners become more or less closely associated with quackery, even of the most blatant quality, in pure ingenuousness. These men are not to be blamed. They are the product of a faulty system of medical education and examination. After years of attendance at a medical school, they remain virtually uninstructed in the fundamental facts of science, and unenlightened as to the methods of scientific reasoning. They do not recognise that in a question of treatment an indisputable diagnosis is the first indispensable requirement; they do not perceive in a question of therapeutics the glaring pitfalls which beset the way in a *post hoc, propter hoc* line of reasoning. With a simplicity equal to that which marks the uninstructed public, these practitioners show themselves willing to accept the word of the nostrum-monger for the efficacy of his wares, and, having administered these concoctions in cases the nature of which has not been scientifically established, they are ready to testify confidently that an apparent improvement or cure has been brought about by the use of medicaments which could have been easily proved by analysis to contain no agent capable of causing physiological reaction of any kind.

This attitude of legally qualified men has had a great effect upon the newspaper Press. Many leading papers have up to now been defenders of scientific medicine; many of them have on every suitable occasion denounced quackery and all kinds of questionable practice. These powerful journals have now mostly altered their position and tone. They obviously argue, that if quackery is capable of affording relief where orthodox medicine fails; if secret remedies may contain ingredients unknown to science and capable of curing diseases which "orthodox" medicine regards as hopeless; and if these facts are testified to by a cloud of lay and skilled witnesses, they, the newspapers, are not called upon to decide, and have no right to exclude from their columns medical advertisements of any description. Some papers are already going further. They are espousing the cause of quackery and holding up as martyrs men whose names have been struck off the *Medical Register* for associating themselves with it. And it must be remembered that the papers are dividing between them an income of not less than £2,000,000 a year from quack advertisements. A great number of papers are owned by companies, and their business managers are not likely for sentimental reasons to deprive their shareholders of dividends to be gained by any means which, at least from the view of commercialism, seem perfectly legitimate.

The appointment of a Select Committee on Patent Medicines has rendered extremely remote the setting up of a Royal Commission. A Royal Commission has power to compel the attendance of witnesses and examine them on oath. A Select Committee's powers are comparatively limited; its report must prove to a like degree inadequate. If, however, legislation from this or any other source be recommended, it will be next necessary to gain the active support of the Government, and to find a statesman both able and willing to study the subject and take charge of the Bill. The days are long past when a private member could introduce and carry such a measure. Legislation would be strenuously opposed by the great bulk of the newspaper Press, and by its representatives in both Houses; by the quacks and owners of quack remedies—wielders of an income of some millions a year and having also backers in Parliament; it would be fought against by the various parties that hate science in general and medical science in particular, as, for example, the anti-vivisectionists and the anti-vaccinationists—all represented in Parliament. All these opponents would use the facts and arguments in support of "free trade" in medicine, which have latterly been so abundantly furnished from many quarters, including the section of qualified medical men to which I have already alluded. In view of all these considerations, it must appear extremely unlikely that any Government will, under present conditions, undertake the task of medical

law reform, and virtually impossible that a satisfactory measure can be placed upon the Statute Book.

In consequence of judgments in the High Courts, confirmed by the House of Lords, the penal clauses of the Medical Acts have been reduced to a dead letter, and there remains no power to prevent quacks from assuming the title of "doctor" and palming themselves off as qualified men in any department where profitable fraud can be most easily carried on.

We are now witnessing what is only the beginning of a great boom in quackery. Quackery provides, at the present day, perhaps the safest of all fields for cynical knavery. It is only the most stupid of quacks who can put himself within reach of the law, whereas a City shark or swindler stands in constant danger of a criminal charge. Quackery affords large incomes to great numbers of vulgar impostors, and vast wealth to many clever adventurers, and is, therefore, becoming more and more attractive to these classes. The Stamp Duty returns show that the sum spent on quack medicines increased from £2,764,557 in 1907 to over £3,500,000 in 1911. It is not necessary to suggest that they are all alike worthless, and that none is efficacious for the purpose for which it is offered. It is enough to state that only a small percentage of these remedies has any value whatever. If the money spent on worthless apparatus and the incomes of unqualified practitioners be roughly guessed, an approximate estimate may be made of the gigantic sum which is annually taken out of the pockets of the simple public. As I have often repeated in previous writings, unqualified practice and the quack medicine trade are not only in the greater part fraudulent, they are cruel and deadly. They give rise to a vast amount of avoidable suffering; they lead to a large preventable mortality. Evidence of this can be found abundantly in every hospital, and can be furnished by every practitioner of sufficient experience. The injury is mostly brought about through reliance upon worthless remedies in cases which are amenable in an early stage to treatment, but which soon pass, if neglected, into an incurable or mortal phase. The injury may be comparatively slight, as, for example, when a case of simple alopecia runs on to complete baldness, whilst trust is being placed in a magic hair-grower. On the other hand, similar delay may condemn the patient to a lingering death, with unspeakable torment, easily preventable by early scientific treatment, as when a heal-all ointment is employed as a remedy for cancer or lupus. Direct injury from quack remedies is not so frequent, but is sufficiently common. It is, for instance, difficult to estimate the injury to health now being caused by sham tonics containing large doses of alcohol. Hundreds of thousands a year are being spent in the advertising of these poisonous compounds—a measure, at least, of their consumption by the simple public.

Every quack enterprise is now being stimulated, and the people, especially the less educated classes, are being led more and more to take the appearance of quack advertisements in high-class journals as a voucher for the good faith of the authors. The simple, confiding masses will be the worst sufferers from the prevailing medical anarchy. The effects upon the profession will be various. From the sordid point of view doctors will not lose much. Quackery causes widespread injury to the public health; the majority of its victims, with maladies created or aggravated by wrong methods, gravitate sooner or later into the hands of qualified men, and thus money which otherwise would not have been earned falls into the pockets of the profession. On the other hand, quackery involves depreciation of medical science and disparagement of its votaries, and the vast increase of advertising must have its effect in this direction at least upon the ignorant reader. And again, the significance of the association of qualified men, either innocently or consciously, with quackery will be recognised by people of higher education, and their respect for the profession must be surely diminished. The distrust thus engendered will hurt most seriously the average general practitioner.

If it is to be classed among the minor evils afflicting

latter-day society quackery must be reckoned among the greatest of these, whilst the association with it of the bulk of the newspaper Press—the self-appointed censors of morals, protectors of the people, guardians of the national honour—must be regarded as one of the most shameful and lamentable scandals of the present day. It seems to be clearly the duty of the profession on humanitarian grounds alone, and in spite of misrepresentation or calumny, to keep up the fight against quackery. Medical men alone know the facts; they alone are able to collect and marshal them and force them into notice. For the time a check is being felt—quackery has gained a temporary triumph. The situation can, I believe, be retrieved by resolution and perseverance; but, as this article is already long enough, further discussion must be reserved for a future communication.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

STRICTURE OF URETHRA—RETENTION OF URINE—WHEELHOUSE'S OPERATION.—MR. WILLMOTT EVANS operated on a man, æt. 47, for stricture of the urethra. The patient had suffered for many years from difficulty in micturition caused by a stricture, and on one previous occasion he had had retention of urine. A fortnight before admission into the hospital, after he had been drinking freely, the difficulty of micturition had greatly increased, but still he had succeeded in passing water after much straining. Two days before admission he found that he was unable to pass any urine at all, and after suffering great pain he came to the hospital. Attempts were made to draw off the urine, but the catheter could not be introduced, as it was arrested about an inch in front of the membranous urethra. As the pain was great, the house surgeon aspirated the bladder by passing a fine hollow needle above the pubes. Nearly two pints of urine were drawn off. It was cloudy and alkaline in reaction. He was given a saline purgative and was kept in bed. The purgative acted well, but he was unable to pass any urine by the urethra, and in the evening of the day after admission it was found necessary to evacuate the contents of the bladder once more supra-pubically. Mr. Evans decided to perform a Wheelhouse operation; so the next morning the patient was anaesthetised and placed in the lithotomy position. The perinæum was shaved and painted with 2 per cent. solution of iodine. A straight Wheelhouse staff was introduced into the urethra as far as the stricture and was held in that position by an assistant, and a scalpel was passed through the tissues of the perinæum so as to enter the groove about half an inch from the stricture. The staff was turned round so that the hook caught the anterior angle of the opening. A fine silk stitch was placed in each edge of the wound, and these were drawn sideways, so that a diamond-shaped opening was formed, through which a fine probe-pointed director was passed, and after a little searching it was found possible to insert the director in the stricture, and it was then passed backwards into the bladder. The point of a knife was inserted in the groove of the director and with it the stricture was completely cut through. As the probe-pointed director was withdrawn a probe-pointed gorget was passed in its place backwards into the bladder. A soft rubber catheter was introduced through the meatus and brought out through the perinæal wound, and then the point was re-introduced and passed backwards along the groove of the gorget until it entered the bladder, and that it did so was shown by the escape of urine along the catheter. The catheter was tied in position, and gauze dressing was applied to the perinæum, the wound being left unsutured.

The patient was returned to bed, and by means of a piece of glass and rubber tubing the urine was conducted to a bowl under the bed.

Mr. Evans said there are certain strictures which need operative treatment, though most strictures of the urethra can be cured by means of one or other form of dilatation. When, however, the surgeon has to deal

with retention of urine combined with a stricture that will not readily admit the passage of a catheter, however small, it is advisable to relieve the retention and at the same time to cure the stricture, and especially is it desirable in those cases in which there is a long history of difficulty of micturition, for in such cases there will certainly be a good deal of dilatation of the bladder, of the ureters, and of the pelvis of the kidneys, while the kidney substance will have undergone a fibrous change which will have interfered in no small degree with the excretory powers of the organs. In such circumstances the kidneys are very intolerant of interference with any part of the urinary system, therefore any attempt to cure the stricture should give complete ease of micturition so as to relieve the over-pressure which has been existing in the urinary tract. In his opinion no operation more completely fulfilled these requirements than that devised by Wheelhouse. It is not difficult of execution, but care should be taken not to make the common mistake of opening the urethra too close to the stricture. It is essential that the opening into the urethra should be made where the urethra is normal, and not where its shape had been altered by scar tissue.

The patient rapidly improved, the urine drained freely through the catheter, and the perinæal wound closed steadily until, about three weeks after the operation, it was almost healed, and a few days later the catheter was permanently withdrawn; but every other day for another week, a gum elastic catheter was passed, and the patient was told that he must attend regularly, at first once a week, later once a fortnight, and later still once a month, in order to make it certain that the stricture was not reforming.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

MEETING HELD FRIDAY, DECEMBER 13TH, 1912.

The President, SIR WM. OSLER, in the Chair.

DEMONSTRATION OF CASES.

DR. A. M. GOSSAGE showed a case of Obstruction of the Superior Vena Cava. The patient, a man, æt. 74, was admitted into the hospital for general malaise. He had had syphilis in his youth, and later had had a gumma on the left upper arm, where there was a scar adherent to the bone. The enlargement of the veins of the trunk had been noticed for the past twenty years. Except that he was rather feeble there was no impairment of his health, and he did not suffer from dyspnoea on exertion. On examination there was no enlargement of the heart and no murmurs. The radial arteries were not materially thickened, being remarkably good for his age. The maximum blood-pressure in the brachial artery was 140 mm. Hg. Over the front of the thorax and abdomen were several chains of enormously enlarged and tortuous veins, extending as high as the second ribs, the largest being on the right side. The blood flow in these veins was from above down and they disappeared at the groins. There were no veins at the back of the thorax. The veins of the lower limbs were varicose, and here, of course, the flow was upwards. There was no swelling or congestion of the face or upper limbs, though the brachial veins were rather prominent. X-ray examination showed no abnormal shadow in the thorax.

The case seemed to be one of occlusion of the superior vena cava, probably due to cicatricial contraction after a gumma in the upper part of the thorax. The enormous enlargement of the veins evidently allowed a free return of the blood from the upper part of the body by way of the inferior vena cava, and explained the absence of the usual congestion of the face and arms when the superior vena cava is blocked.

Mr. RALPH THOMPSON showed two cases of Prostatic Calculi, with skiagram.

Case I.—A man, *æt.* 67. At the end of November, 1911, examination with a sound revealed a stone; it was apparently felt with the shaft of the instrument, the beak of which was free in the bladder. Rectal examination showed the stone in the region of the prostate. An operation was done by the perineal route in front of the transversus perinei on December, 1911; the capsule of the prostate being incised and the stone removed, the wound healed well; weight of the stone, 32.5 gm. Composition of the stone: one large and three small faceted pieces. The skiagram was important as showing the surface markings of the prostate, and the position of the prostatic stone. The patient appeared perfectly well.

Case II.—A man, *æt.* 73. He was admitted for difficulty in passing water on October 30th, 1912. Catheters passed with some difficulty. Suprapubic cystotomy under spinal anæsthesia was done. After operation, some difficulty was experienced in passing catheters occasionally, not always. On November 10th a stone was felt in the region of the prostate with a conic catheter and sound. A skiagram revealed three prostatic calculi lying behind the pubes. Nothing was felt *per rectum* except a very hard prostate. On November 20th he died. *Post mortem*: A double aortic aneurysm was found, the bladder, prostate and urethra were removed for examination and exhibition.

Dr. F. PARKES WEBER showed two cases of Family Cerebellar Ataxia in two half-sisters.

Case I.—A well-grown but somewhat mentally deficient girl, *æt.* 15. She was backward in learning to walk, and her mother said that she never was able to speak distinctly. At the age of six she could not walk and run as well as other children of her age, and tended to fall forwards when excited or if she tried to go too fast. About Christmas, 1908, increasing tendency to fall was observed, and she sometimes had to support herself with her hands when standing. She often complained of headache, and sometimes vomited. In May, 1909, when she first came under Dr. Weber's observation at the hospital, there was decided unsteadiness in gait, especially noticeable when she tried to walk along a marked-out line and when she turned round suddenly. Occasionally there was tremulousness in the limbs and head. No definite Romberg's symptom. Her mother thought that her gait afterwards improved somewhat. In November, 1912, she walked slowly and somewhat unsteadily, placing her feet rather too far out sideways. She tended to "totter" when turning round quickly. Romberg's sign was negative. Patellar, Achilles, plantar, abdominal, and pupillary reflexes were normal. There was occasionally fine horizontal nystagmus on looking to right or left. No muscular wasting; no anæsthesia; no "pes cavus"; no deformity of the vertebral column. Her speech was slow and monotonous. She was clean in her habits. Nothing abnormal in the thoracic or abdominal organs, or in the urine. The Wassermann reaction for syphilis was negative with the patient's blood serum. The hearing was good. Nothing abnormal was seen by ophthalmoscopic examination.

Case II.—A well-nourished but somewhat mentally defective girl, *æt.* 4, half-sister (by her mother) of the first patient. She was said to have begun to speak when aged 2½. She used to get about, her mother thought, like other children of the same age. In November, 1911, she had a sore throat, and in January, 1912, she was brought to the German Hospital out-patient department because she had almost lost the power of walking. At that time her knee-jerks were found to be normal. In February, 1912, she could walk about, but with a paretic-spastic gait, and the knee-jerks were excessive. After that improvement was said to have occurred, but in July the child had an attack of follicular tonsillitis with fever, and the gait became worse again. When admitted to the German Hospital (July 15, 1912) the child could not walk or stand without support. Her gait was of an unsteady, paretic-spastic type, and she preferred to place her feet a good deal apart when

standing up. There was evidently some deficiency in the balancing power. Marked tremulousness occurred in the upper and lower extremities when walking; the movements of the upper extremities were rather slow and showed no marked ataxia. The knee-jerks were readily obtainable, and were, if anything, rather excessive. The plantar reflexes were of the extensor type in both feet. The pupillary reflexes were normal, and there was no nystagmus. Ophthalmoscopic appearances were normal. The child spoke very little, and only in a slow, monotonous way. No muscular atrophy; no definite signs of rickets. Nothing abnormal in the thoracic or abdominal viscera. Since July there had been some improvement, and the plantar reflexes were found to be of the normal flexor type, when tested at the end of September.

In both the actual ataxia was very slight. In the eldest patient the chief symptom was the tendency to "totter" on walking and turning round sharply. In the second case the spasticity of the gait and the presence of Babinski's phenomenon in July pointed to involvement of the cerebral motor cortex as well as of the cerebellum, the symptoms being those of what one might term a mild cerebro-cerebellar diplegia.

No history of nervous disease in other members of the family can be obtained, but the subject was rather difficult to investigate, as the mother, a healthy-looking and apparently mentally normal woman, aged 41, had had children by three different men.

Dr. F. PARKES WEBER also showed a case of bilateral cervical ribs with unilateral (right-sided) atrophy of hand muscles. The patient, *æt.* 21, was a well-built young woman. Four years ago she fell on her right side; she noticed nothing specially wrong till a year later, when she began to suffer from pain in the right upper extremity, and there was some wasting in the right hand. The pain was of a "burning character," passing from the right shoulder along the inner and back part of the arm to the elbow and down the ulnar side of the forearm to the wrist and ulnar side of the hand. This pain, though not always present, had troubled her on and off since then, and lately she had likewise had pain of a more biting character on the ulnar side of the affected hand. The wasting in the right hand had somewhat increased since it was first observed. She said that when she was exposed to cold weather her right hand was more numbed and bluer than her left hand, but she did not think her right hand became definitely weaker in cold weather. When shown there was marked atrophy of the intrinsic muscles of the right hand; it was seen in front of the thenar and hypothenar eminences and at the back in the region of the interosseal muscles between the metacarpal bones. The distal part of the right forearm appeared slightly smaller than the corresponding part of the left upper extremity. The dynamometer grasp was 7½ in the right hand against 15½ in the left hand (the normal grasp by the dynamometer in question would be about 15 to 20). Electrical examination with the galvanic current showed that ACC was greater than KCC in the muscles of the thenar eminence of the right hand, whereas in the corresponding muscles of the left hand KCC was greater than ACC. There was no anæsthesia or hypo-æsthesia in the hand and forearm of either side. Skiagrams showed that the patient had a small seventh cervical rib on each side, though these could not be felt by palpation in the neck. Nothing else abnormal had been detected in regard to the patient, except that from childhood she had had slight "dysarthria" in regard to the pronunciation of certain consonants. The brachial systolic blood-pressure was slightly greater on the affected side than on the unaffected. There was no scoliosis and no abnormality in regard to sweating, pupillary reactions, or tendon reflexes, and, when she was not exposed to cold weather, there was no difference in colour and temperature between the two hands.

Symptoms due to seventh cervical ribs were commoner in females than in males, and usually first showed themselves about the time of puberty, as they did in the present patient. When, in cases of bilateral cervical ribs, the symptoms were only unilateral, Dr.

Weber believed that they were usually (as in the present case) on the right side. The slight dysarthria (defect in the pronunciation of certain consonants) observed in the present case represents a faulty development in an important function, which might be compared with faulty developments in structures of the body (such as the development of cervical ribs), since they both belonged to the class of abnormalities which had sometimes been included as "stigmata of degeneration." An occasional association had been claimed for cervical ribs with other malformations (Oppenheim), such as the presence of medullated nerve-fibres in the retina, and also with various "degenerative" nervous diseases, amongst which might possibly be classed Graves's disease and syringomyelia. On the other hand, cervical ribs were not very rare, for they often gave rise to no symptoms (so that their presence was not inquired into by Röntgen-ray examination), and the association might be a chance one. Moreover, symptoms connected with cervical ribs might occasionally have been supposed to indicate the presence of syringomyelia, when the latter disease was not really present.

Dr. F. PARKES WEBER also showed a case of cervical ribs with atrophy of hand muscles. The patient, *æt.* 16½, was a well-nourished girl, who first came under Dr. Weber's attention when she was aged 13, for symptoms suggesting the presence of seventh cervical ribs. The symptoms were almost entirely confined to the right upper extremity. There was decided wasting of the thenar, hypothenar, and inter-metacarpal regions of the right hand. The right hand was weaker and usually felt colder than the left hand. Exposure to cold made it still weaker, and it more readily became numbed than the left hand. The dynamometer grasp in the right hand was 5, and in the left hand 15 (the normal grasp by the dynamometer in question would be about 15 to 20). Electrical examination by galvanism showed reaction of degeneration in the muscles of the thenar and hypothenar regions of the right hand. There was decided hypo-æsthesia on the ulnar side of the right upper extremity, notably in the hand. A skiagram showed the presence of a small seventh cervical rib on each side, but the one on the right side was the bigger of the two. Neither of them could be detected by ordinary palpation. The wasting in the hand muscles had been observed during the previous two or three months only, but pain of a sharp, shooting character in the right upper extremity had been occasionally complained of for the last two years. The knee-jerks and Achilles-jerks were normal. In this case the symptoms due to cervical ribs first attracted attention, as usual, about the period of puberty, for menstruation commenced when she was aged 13.

The right seventh cervical rib was removed by Dr. E. Michels on May 14th, 1909, and since then the patient had never had the peculiar pain she complained of in the right upper extremity. After the operation, however, she at first lost power in her right hand. This gradually returned, until the dynamometer grasp (the same dynamometer used as previously) with her right hand was 11, against 26 with her left hand. There was still much wasting in the intrinsic muscles of the right hand, and her weakness caused difficulty in writing, etc., for she had not become left-handed. The electrical examination with galvanism showed that ACC was greater than KCC in the muscles of the thenar and hypothenar regions of the wasted hand. During exposure to cold the right hand still became more readily numbed than the left hand, and there was still decided hypo-æsthesia over the ulnar portion of the right wrist and hand, including the fourth and fifth fingers. Before the operation the patient was shown at the meeting of the Medical Society of London, on April 26th, 1909. A skiagram of the neck showed the appearance after the operation.

Mr. PHILIP TURNER showed a case of sarcoma of foot. The man, *æt.* 72, first noticed a swelling of his right foot 34 years ago. He said that it appeared after an attack of rheumatism. Though slowly increasing in size, it gave him no particular trouble until recently, when the enlargement had been more rapid. Two months ago the skin at the posterior part gave

way, and the resulting ulcer had never healed. There was a large tumour, the maximum length of which was 4 in., situated at the posterior part of the sole and the outer side of the right foot. Posteriorly there was an ulcerated surface the size of half-a-crown, from which a fungating mass protruded. The tumour was elastic in consistency, and appeared to be adherent to the os calcis. Radiographic examination, however, showed this and the other tarsal and metatarsal bones to be unaltered. There was a small area of ossification near the centre of the tumour.

Dr. W. ESSEX WYNTER, M.D., and Mr. JOHN MURRAY showed a case of subcutaneous drainage for ascites. The patient, a woman, was admitted on August 30th, with a history of peritonitis and colic nine years before, followed by enlargement of the abdomen. She had attended the out-patient department for three months on this account, increase in the size of the liver and spleen being noted. She had suffered with symptoms referred to the liver for three years, with occasional diarrhoea, vomiting and hæmatemesis, and had been losing weight. There had also been complaints of numbness and loss of power in the hands, with shooting pains in the legs. She was thin, with earthy complexion and stigmata on face, the knee-jerks were feeble, and there was some arterial degeneration. On September 17th, the abdomen being very tense and respiration hampered, 9 pints of fluid were withdrawn; measurement, 34½ in.; the enlargement of the liver and spleen being then obvious. Fluid rapidly re-accumulated, and by October 10th she was tenser than before; measurement, 35½ in. On October 18th an incision was made in the mid-line below the ensiform cartilage, and a decalcified bone tube inserted into the peritoneal cavity, its free end being buried in the parietes. The skin was then sutured over it. The hob-nailed surface of the liver was felt, leaving no doubt as to cirrhosis, some fluid escaped, and considerable leakage occurred afterwards. Owing to delay in healing, and the occurrence of some suppuration, the bone tube was withdrawn 14 days later. Measurement, 26½ in. Temperature throughout ranged from 97° to 100° F. Fluid had not re-accumulated.

Dr. R. HUTCHISON showed a case of Hirschsprung's disease. This patient was shown at the last meeting, and was exhibited again to show the result of treatment by brine enemata. The abdomen had become quite flat.

Dr. A. F. HERTZ showed a case of organic hemiplegia following typhoid fever, in which the plantar reflex was flexor, but Babinski's "second sign"—combined movement of the trunk and pelvis—was present. The man, *æt.* 31, had typhoid fever in 1902. At the end of the second week of his illness he woke one morning to find that the left side of his face and his left arm and left leg were paralysed. The paralysis diminished for a time, but after some months no further improvement occurred.

There was, when exhibited, very little evidence of facial paralysis, and the arm had recovered most of its power. The left leg was still weak and spastic, the knee-jerk was increased and ankle clonus was present. The evidence, so far, is strongly in favour of the case being one of organic hemiplegia, due probably to cerebral softening following thrombosis occurring during typhoid fever. It was therefore expected that the left plantar reflex would be extensor, but it was quite definitely flexor. The organic nature of the hemiplegia was, however, proved by the presence of the "combined movement of the trunk and pelvis," described by Babinski, which Dr. Hertz had called, for convenience, "Babinski's second sign." The patient, lying flat upon his back, with his arms folded across his chest and his legs widely separated, was told to rise to the sitting position without using his arms. At each attempt to do so the paralysed leg rose, the other leg remaining on the floor or rising considerably less high. The same thing happened to a less marked degree when the patient fell back from the sitting to the dorsal position.

Babinski was the first to point out that the paralysed leg remained flat on the floor in hysterical hemiplegia, whereas in organic hemiplegia it always rose higher

than his fellow. In Dr. Hertz's experience the sign was of great value, as he had several times obtained it when the plantar reflex was unobtainable, and also in children under the age of 3 in whom the plantar reflex was normally extensor.

Mr. THOMAS H. KELLOCK showed a boy after pneumotomy for foreign body in the right lung, and read a short paper on the case. The foreign body, a large pin, has been inhaled to the base of the right lung. After bronchoscopic methods had been unsuccessful, Mr. Kellock cut down upon the lung, turning up a large flap of the thoracic parietes at the right base. He then incised the lung from its diaphragmatic surface and removed the pin, which was embedded in lung tissue. No empyema existed or followed. The operation had been followed by good recovery.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

MEETING HELD THURSDAY, DECEMBER 5TH, 1912.

The President, DR. AMAND ROUTH, in the Chair.

A SHORT communication was read by Mrs. WILLEY, M.D., on a case of
HYDROCEPHALUS COMPLICATED BY ECLAMPSIA, FIBROIDS,
AND A CONTRACTION RING.

The patient, who was 37 years of age and a primigravida, was first seen in the seventh month of pregnancy, when slight œdema and albuminuria were present, but these symptoms disappeared under treatment. The fibroids were subperitoneal and situated near the fundus. Pregnancy went to term, but the membranes ruptured ten days before labour; the presentation was a footling. Six or seven hours after the onset of pains an eclamptic fit occurred, followed by two others at intervals of half an hour. The urine now contained a good deal of albumen. The legs, body and arms were delivered by traction, and it was then found that the descent of the head was arrested by a firm ring of contraction round the neck. Above the ring intermittent contractions could be felt in the body of the uterus; the cord had ceased to pulsate. A large mass could be felt in the uterine cavity, but whether this was a fibroid or the enlarged head could not be made out. The spinal canal was accordingly punctured in the lower dorsal region, and cerebrospinal fluid flowed out freely. Traction was now steadily kept up, and in 20 minutes the contraction ring yielded and the head was delivered. Two more fits occurred after delivery. The temperature was over 100° for three days, and there was some jaundice, but in the end her recovery was satisfactory.

Dr. CLIFFORD WHITE read a paper on

THE CONTRACTION RING AS A CAUSE OF DYSTOCIA,

in which he contrasted the clinical picture given by these cases with those where a retraction ring forms as a result of obstructed labour. The chief points are: That with a contraction ring, (1) the lower uterine segment is not thinned or over-distended; (2) the ring forms over a depression in the outline of the child or below the presenting part; (3) the general condition of the patient remains quite good; (4) the body of the uterus as a rule remains relaxed and not tender; (5) the presenting part is not forced down into the brim; (6) it may occur before rupture of the membranes.

The most important causes of the condition are: (1) Premature rupture of the membranes; (2) intra-uterine manipulations; (3) malpresentations.

The treatment in severe cases is difficult. The slighter cases are best treated by manual dilatation of the ring with the fingers, but if these means fail it may be necessary to perform Cæsarean section, as forceps fail and embryotomy is usually very difficult. The reason why both these means fail is because the ring, being tightly round some depression in the child, will not let the child move except with the uterus, and thus traction by forceps merely drags the uterus as a whole towards the vulva. If craniotomy is performed, cleidotomy must also be done to enable the shoulders to pass the ring, which is usually round the neck. A

further difficulty in performing embryotomy is that the proportion of macerated children is high (10 per cent.), and so any portion of the child on which traction is made usually pulls off. If Cæsarean section is performed the incision will usually have to be continued downwards till the ring itself is divided before the child can be extracted. The most difficult cases to treat are those where the uterus is infected. (Statistics seem to show that infection of the uterine contents is frequent in these cases and may be a factor in its causation.) In these cases, if the child is alive Cæsarean section, followed by hysterectomy, is indicated. The extra-peritoneal operations would not be possible owing to the length of the incision required. If the child is dead and the mother is infected it may be necessary to excise the gravid uterus, as the recorded cases show that the embryotomy is a particularly difficult one and attended by a high mortality. He reported three cases: the first was treated by embryotomy, which was very difficult, as the child was wholly above the ring and a placenta prævia prevented access. The mother died with a ruptured uterus. The second also had a placenta prævia, but was delivered by craniotomy and cleidotomy. The ring was wholly below the child. The mother recovered. The third case was one with a transverse presentation with the ring firmly contracted round the prolapsed arm so that even the finger could not pass it. The child being dead, and the mother having had five other living children, and being infected, the case was treated by excising the gravid uterus unopened. The mother did well. The uterus, after hardening, shows the ring formed round the child's neck and constricting it. The ring is most marked where the fetal parts allowed constriction—*e.g.*, the neck—and became less marked over points of greater resistance—*e.g.*, the arm. It thus shows the great importance of the fetal outline in determining the existence and site of the ring. Measurements of the specimen show that there is no thinning of the lower uterine segment. Details of 18 cases treated by laparotomy are given.

The paper was discussed by the President, Dr. Handfield-Jones, Dr. Griffith, Dr. Eden, Dr. Williamson, Dr. Russell Andrews, Dr. Willett, Miss Aldrich Blake, and Dr. Eardley Holland.

LIVERPOOL MEDICAL INSTITUTION.

CLINICAL MEETING HELD THURSDAY, DECEMBER
5TH, 1912.

The President, MR. ROBERT JONES, in the Chair.

NUMEROUS cases were shown by the members, and Dr. STOPFORD-TAYLOR and Dr. R. W. MACKENNA presented a paper on

IONIC MEDICATION.

The authors explained the principles upon which ionic medication depends, and showed how in dilute solutions of salts there are present three varieties of elements—*viz.*, positively charged metallic radicles, negatively charged basic radicles, and neutral molecules of the salt. The ions of metals, the hydrogen ion of acids, and the alkaloids carry a positive charge of electricity, and may therefore be introduced into the body under the positive electrode. The metalloids and non-metals, the halogens and the hydroxyl ions of alkalis are negatively charged, and are introduced under the negative electrode.

Penetration through the skin is chiefly through the glandular orifices, the current choosing the path of least resistance. The depth of penetration is dependent upon the intensity of the current and the duration of each treatment.

Some of the ions, especially those of the heavy metals, enter into new combinations with the albuminous fluids of the body and are precipitated. Others combine with the salts in the tissue cells, while others pass into the tissues in the soluble state and are rapidly diffused.

The ions of all the heavy metals are more or less

caustic. In large doses they are destructive, in small doses stimulating. The zinc ion is a very powerful coagulator of albumin. The action of the chlorine ion is entirely different from the action of free chlorine, which is a powerful oxidiser and antiseptic. Ionised chlorine has the power of softening cicatricial tissue.

In applying treatment the pads used must be thick and well saturated; the metal electrode should not touch the skin at any point; the skin must be free from abrasions; all breaks in the continuity of the conductors must be eliminated, and the current must be introduced and cut off very gradually.

The widest field for the application of ionic therapy is dermatology. The zinc ion gives excellent results in the treatment of lupus vulgaris, the resulting scar being soft, pliable and elastic, and differing only slightly in colour from the normal skin. Ionisation with zinc is the best method of treating intra-nasal lupus. The zinc ion will also cure many cases of rodent ulcer, and cocco-genic syco-sis may also be treated with this ion. The chlorine ion will cure alopecia areata. Ringworm of the scalp may be treated with the iodine or mercuric ion. The copper ion has been used for lupus erythematosus, and the magnesium ion will cure multiple warts. Pigmented stains may be removed from the skin by ionisation. The advantages of ionic medication are the ease of applying it, its comparative painlessness, and the fact that it enables us to introduce remedies into the actual protoplasm of the cell. Even greater results may be expected from ionic medication when some of the radio-active salts have been pressed into service.

Among the cases shown and bearing on the paper of the evening, Dr. Stopford-Taylor and Dr. R. W. MacKenna showed a large number of patients suffering from skin diseases. The most interesting were: (1) a girl, *et. 8*, with three varieties of tubercular lesions—viz., lupus pernio, affecting the fingers, lupus erythematosus, and pulmonary tuberculosis. Von Pirquet's test, positive.

(2) A man suffering from Darier's disease. Under treatment with the X-rays very marked improvement has been obtained, as shown by photographs taken before treatment was begun.

(3) A case of lupus verrucosus, treated with zinc ions. The soft and pliable scar, of almost normal colour, was a striking feature. Photographs of the hands, showing the great extent of the disease before treatment were also exhibited.

(4) A case of chlorine acne in a chemical labourer. The whole trunk of the patient before treatment was covered with large sebaceous cysts, which were removed by excision. The smaller lesions had been treated with the X-rays with great success.

Two cases of extensive favus, a case of scleroderma, and a case of ichthyosis were also shown, as well as a large number of interesting photographs and wax casts of cutaneous affections.

Ointments of oxide of zinc and menthol can also give relief, and, in certain bad cases, Mr. Gaucher, prescribes syringing with:—

Chloroform, 1 oz.
Spirits of camphor, 1 oz.
Sulphuric ether, 1 oz.
Menthol, 2 drs.

When the local treatment does not suffice to remove the itching, the nervous condition should be relieved by preparations of valerian:—

Valerianate of ammonia, $\frac{1}{2}$ dr.
Tincture of valerian, 2 drs.
Peppermint water, 3 oz.

A teaspoonful night and morning.

Insomnia will be treated with chloral, trional, veronal or bromide of potassium.

Quinine in five-grain doses twice a day acts frequently as a specific, while chloride of calcium will also be found useful in the chronic form of urticaria.

CUTANEOUS STREPTOCOCCIA.

Impetigo of the face, head and body is frequently observed in children of the poorer class, and is due to inoculation by the streptococcus and easily transmitted by contact, hence its prevalence in schools.

According to Dr. Sabouraud, who made a particular study of this affection, the local treatment is essentially that of the applications of a slightly caustic solution of zinc and copper followed by zinc ointment:—

Spirits of camphor, 2 drs.
Sulphate of copper, $\frac{1}{2}$ dr.
Sulphate of zinc, 1 dr.
Water, 10 oz.

All the crusts are removed with this liquid and the raw surfaces touched with caustic three or four times a day, after which the ointment is applied.

In phlyctenular conjunctivitis a few drops of the following solution are instilled night and morning:—

Sulphate of copper, 4 grs.
Water 3 oz.

Streptococcal infections of the natural folds of the skin, as well as impetigo of the corner of the mouth, edges of the nose, behind the ears, is best treated by:—

Proot spirit, 4 oz.
Tincture of iodine, 1 dr.

Rupia ecthyma should be treated by baths, good food and rest, while the caustic solution of sulphates of zinc and copper is freely applied, and finally:—

Sub-carbonate of iron, $\frac{1}{2}$ dr.
Vaseline, 2 ozs.

A REMARKABLE DISCOVERY OF A CRIME.

On November 2nd, a woman belonging to the unfortunate class was found strangled in a retired spot of the Bois de Boulogne. The doctor charged with the autopsy remarked, besides the ordinary signs of strangulation, a piece of skin held firmly between the teeth of the victim. He laid it aside carefully wondering where it had come from.

The following day, commotion was excited in a fashionable quarter of Paris by the suicide of a gentleman, over 50 years of age, of noble extraction. A note in the handwriting of the suicide was left in evidence on the table stating that he committed suicide on November 2nd. This unusual declaration led the family doctor, who was called in, to carefully examine the body, and he came to conclusion that the suicide took place on November 3rd and not the previous day as pretended. Why this false statement? But the inquiry reserved other surprises.

More minute examination of the body revealed the existence of a wound of curious form on the penis; a part of the prepuce was missing! The extraordinary discovery was brought to the attention of the police authorities, and the following day the Press mentioned the fact in covered terms. When the doctor who had made the autopsy of the woman read the report, he remembered the piece of skin he had found in the mouth of the corpse and brought it to the police who found that it exactly adapted itself to the solution of continuity found on the genital organ of the count; thus, the whole mystery was cleared up. The count, by anticipating his suicide, wanted to create a posthumous

URTICARIA.

No matter what may be the cause of urticaria, there exists a certain number of remedies to allay the intolerable itching provoked by the eruption.

These are: lotions, powders, ointments and cotton wool dressing. Baths, starch or alkaline, says Dr. Gaucher, are more hurtful than beneficial in urticaria. On the other hand, lotions of hot water to which is added one third of vinegar or a one per cent. solution of phenic acid with a little glycerine, relieve very well the patient; if, however, these lotions fail to suffice, sedative powders are applied:—

Powdered starch, 3 oz.
Powdered talc, 3 oz.
Powdered camphor, $\frac{1}{2}$ dr.

alibi, so as to leave this world with his reputation intact, but it was evident that he was the assassin. The fact was still further confirmed by a witness, who stated that the count was in the habit of frequenting a certain class of girls in the Bois de Boulogne for the purpose of practising unnatural acts.

Here is an instance of how legal medicine can reveal facts which would easily have passed the notice of a superficial observer, and seem incredible if they were not founded on positive evidence.

GERMANY.

Berlin, Dec. 14th, 1912.

THE FRIEDMANN TREATMENT OF TUBERCULOSIS.

THIS matter came up again on an adjourned discussion on the 13th ult. Hr. Friedmann on the occasion added somewhat to his previous pronouncement. He repeated that he had not said what his curative material consisted in. Whether he will act up to the traditions of the noblest of professions, or as a quack—keep his secret and *sell* it to the highest bidder, and so make a fortune for himself out of it, still remains to be seen. "I have thoroughly tested many and many a kind of avirulent cultures, also such as were obtained from the human subject, that had been rendered avirulent by various methods, but I have quite given them up."

In fact, he had made use of the most varied non-virulent kinds—those from warm-blooded animals that had been made avirulent, others from the most diverse cold-blooded ones. In 1903 he had published results of investigations into tortoise tubercle. In 1904 he made a further communication on a second tortoise strain. If the first strain was only slightly virulent, it set up nodules in the guinea-pig that never led to tuberculosis; still the nodules could be felt year after year. A third strain was discovered, a natural one that showed avirulence in a high degree, and concerning this he had never published anything. Even in its natural state it was perfectly harmless for guinea-pigs, it caused scarcely any nodules, and in a short time it lost the last trace of virulence. He then used the preparation more extensively, and on the human subject. His preparation was, therefore, perfectly harmless for guinea-pigs. Animals that had been injected two and three years were perfectly sound and free from nodules. He might also state that he had experimented with other cold-blooded animals, fish, salamanders, blind worms, snakes, also with other tortoises, but, without exception, with results that were not good.

Hr. Erich Müller said they had just heard from Hr. Friedmann that his form of bacillus was not from the human subject or from cattle, but from some cold-blooded animal, the bacilli from which were quite avirulent for man. The recoveries he had seen were such as were not possible by any other known means. He believed also that children injected would be safe from infection. A child shown by Friedmann was very remarkable. Like many similar cases, it showed the harmlessness of the injection, and spoke strongly in favour of the protecting power of the preparation in that in the midst of a tuberculous milieu it had remained free from the infection. The protective inoculation had been then made about a year. For the future—the immediate future, at any rate—they would limit their injections to children that were ill.

Hr. Kausch would ask them to restrain their enthusiasm for the present, and bear in mind Koch's first pronouncement and salvarsan in syphilis.

Hr. Piorskowski related some details of the work he had done for and with Friedmann, and concluded that the culture, some of which he had brought with him to show, looked exactly like human tubercle, and behaved exactly like it in the incubation oven. For that reason he believed that the tubercle from the great tortoise of the Berlin aquarium was of human origin, and was to be reckoned as of the *typus humanus*.

Hr. Aronsohn would like to know the dose given by Friedmann—i.e., the number of bacilli he injected. He could only understand by the simultaneous method

that a smaller dose than usual was given in each, and that the absence of abscess formation was due to the smaller quantity injected.

Hr. Wolff-Eisner said that no proof had been brought forward that the injections were harmless. In that short time it was impossible to say that they were harmless. It was also possible that some of the cases recorded as cured were not really cases of active tuberculosis.

Hr. F. Meyer would like to know whether Friedmann had submitted his cases of cure to the tuberculin test. The cases that had been shown would have got better by tuberculin treatment. He could not take it that Friedmann had said that they were cured. He would raise an energetic protest against protective injections, both on ethical and scientific grounds.

Hr. Bier had seen a number of Friedmann's cases. He must confess that he had received the impression that there was a decided curative action, but he had not so far seen any decisive proof.

Hr. Schwenk said that he could not altogether agree with what Friedmann had said. There was one case which his colleague (Hr. Friedmann) had described as cured. He (Hr. Schwenk) had seen the case the day before. There was no question whatever of a cure, nor even of improvement. The patient was sent to Friedmann in 1911. She had about six injections. In August of last year she was again under treatment, and had two injections. She reacted with a universal urticaria, which lasted for several days. She was no better.

Hr. Katzenstein said that in surgical cases of moderate degree we had in tuberculin such an excellent remedy that we had no occasion to have recourse to an unknown remedy.

AUSTRIA.

Vienna, Dec. 14th, 1912.

ILEUS AND PNEUMATOSIS.

Demner presented a case from Hochenegg's ward, who had been operated on for gastric growth and vomiting. For six years and a-half the patient had suffered from persistent vomiting with severe pain. Under local anaesthesia the patient was operated on and two large emphysematous cysts, each the size of a man's fist, were removed from the right subphrenic region, which pressed the liver beyond the middle line towards the left and compressed the pylorus. The small intestine was enormously dilated to 90 centimetres in circumference of 34.43 inches. Along the external surface of the bowel as well as of the mesentery were strewn large and small cysts like grapes, in some places very densely arranged. The contents of these cysts were mostly gaseous, but where degeneration had set in and the cyst had become cloudy, a serous fluid was present. This degenerative change was mostly confined to the mesentery. It seemed that a number had degenerated to the size of peas, giving the mesentery a shaggy appearance, while others were in threads and plaques.

The histological diagnosis was given as *pneumatosis intestini cystoides*, although the clinical diagnosis was pyloric stenosis from the history of *ulcus ventriculi*, which was not altogether wrong as the stenosis and an old cicatrix in the organ were very prominent with fresh inflammatory areas on the perigastric surface, more particularly on the posterior surface. The ileum and caecum did not escape these changes being affected with a severe form of appendicitis and adhesions. After stripping and removing, the patient has made a wonderful recovery, looking well and feeling strong, as the appetite is good.

ŒSOPHAGEAL DILATATION.

Koffer next brought in a case from Chiari's clinic with enormous widening of the oesophagus and cardiac spasm, for which he was operated on by Heyroldsky. The spasm in the cardiac portion of the channel could not be accounted for. The patient was 33 years of age and had suffered for years from difficulty in breathing and cyanosis in consequence of the great pressure on the trachea.

Gottstein's operation of passing the sound was tried but failed. Gastrostomy was next resorted to, but this failed to relieve the cardiac spasm, but feeding was more easily performed. The bougie could not be passed up the œsophagus nor down, as it was caught at the cardiac end of the organ. Finally he determined to operate over the site of obstruction and found at the hiatus of the diaphragm a band of fibrous tissue strangulating the œsophagus; this was released and the channel opened freely into the stomach. The wound healed up normally in 14 days, while the feeding was conducted by the opening in the stomach, which is now ready for closing also as the patient can swallow without difficulty.

RESECTION OF FEMORAL ARTERY.

Schnitzler exhibited a patient, æt. 23, who had suffered from tubercular lymphoma in the left inguinal region closing the venous circulation by inflammatory adhesions. Before admission an effort had been made to relieve the veins, but in the operation the femoral artery got injured, which increased the lesion. Schnitzler ligatured the veins, but found no pulsation in the femoral vessel, while the leg remained white and dead.

He then determined to resect the injured portion of the artery and unite the free ends of the artery by circular stitching of the vascular walls of the vessel. The operation was quite a success. The circulation in the leg was immediately restored and the limb gradually assumed its natural colour, and the patient feels perfectly well.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE LORD LISTER MEMORIAL.

THE Lord Provost of Glasgow presided over a meeting, on December 11th, of the Executive Committee in the City Chambers, on the proposed memorial to the late Lord Lister.

The Committee had under consideration the remit made to them by the Provisional Committee at their meeting held last week to reconsider the question of the establishment of a Lister Museum in one of the wards of the Royal Infirmary in which Lord Lister first put into practice his antiseptic system of surgery.

Dr. George Middleton moved, and Professor Samson Gemmell seconded, that the Committee do not approve of the establishment of such a museum.

Mr. A. E. Maylard, seconded by Mr. Hedderwick, moved as an amendment that the previous recommendation of the Committee be reaffirmed, namely, that subscriptions be invited, first towards the erection in Glasgow of a suitable monument to Lord Lister and the provision of an endowment for the equipment and maintenance of the proposed Lister Museum at the Royal Infirmary and, second, towards the Lister International Memorial Fund promoted by the London Committee.

On a vote being taken Mr. Maylard's Amendment was carried, and the treasurer reported that since the last meeting he had received several additional subscriptions.

NERVES AND WORRY.

Dr. Alfred B. Olsen, the principal of Caterham Sanatorium, delivered a lecture recently in Glasgow at the Deaf and Dumb Institute, on "Nerves and Worry." Dr. Olsen said that this was an age of restless hurry and worry, and that the conditions of artificial exciting city life were apt to strain and overtax the brain. Life was largely what people made it, and it had been clearly proved that training and environment were more potent factors than heredity. Man was made for work, his muscles, heart, lungs, brain and nerves were given him for use; and the more in reason he used them the more efficient, the stronger and the healthier they became. Normal use of the functions of the body was constructive and vitalising, but worry wasted the vital forces of the body. Worry

has been described as a disease of the twentieth century, and it was a truism to say that it was not work but worry that killed.

In discussing the causes of worry it was found that domestic troubles probably headed the list, but the worries and cares associated with modern business competition were almost of equal importance. In an analysis of 604 cases of neurasthenia, 198 were merchants and manufacturers, 130 were clerks, 68 professors and teachers, 56 students, 38 officers, 33 artists, 19 of no profession, 17 medical men, 17 agriculturists, 10 clergy, 6 men of science and learning, 6 schoolboys, and 6 working men. Alcohol was a nerve poison, and interfered with the work of the brain cells, while tea, coffee, cocoa were drugs. To secure perfect health and sanity it was of great importance to cultivate regular hours and obtain sufficient sleep, for nervous diseases and insanity were on the increase, and it behoved us to take heed to our ways lest we became a nation of invalids.

VACCINATION AND SMALL-POX.

Recently Kirkcaldy has been under the ban of the Public Health Authorities with sporadic cases of small-pox appearing throughout the town. The Health Committee hope that they have now got over the disease. On November 10th there were twelve cases in the hospital, nine convalescent and three improving, while fifteen cases of contacts were isolated in the reception house.

At the monthly meeting the Convener of the Health Committee was asked the effects of vaccination in the present outbreak, and stated that 41 cases of small-pox had been treated in the hospital—40 from Kirkcaldy and one from Dysart. Thirty of these were vaccinated at birth, and of these six had died, including two women who had no chance of living because of their condition, thus showing a mortality of 20 per cent. of deaths of those vaccinated. Eleven other cases were unvaccinated, or showed no signs of vaccination, and of these seven, or about 63 per cent., had died. There were nine cases of contact who refused vaccination or re-vaccination, all of whom developed the disease, and three of these died. Generally speaking, the severity of the disease was in direct proportion to the length of time that had elapsed since they were vaccinated.

GLASGOW DOCTORS AND THE INSURANCE BILL.

Obedying the instructions of the Council of the British Medical Association, meetings of members of the medical profession have been held in Glasgow for the purpose of considering the latest proposals by the Chancellor of the Exchequer for service under the Insurance Act.

Under the presidency of Dr. A. T. Campbell, the members of the North-Western division of the city met in the Burgh Hall, Hillhead, where the question of accepting or declining service was fully discussed, and it was decided by a majority to decline to work under the Act under present conditions.

A meeting of practitioners of the Southern Division was held in the Y.M.C.A. Hall, Eglinton Toll, when a vote of members of the Association and non-members was taken separately, and it was resolved by a large majority to refuse to accept the terms offered by the Chancellor of the Exchequer.

Dr. Robert Jardine presided over a good attendance of members and non-members of practitioners in the Central Division, held in the Faculty Hall; it was decided by a majority to render service under the present terms.

A meeting of the Stirling Branch of the British Medical Association was held on Tuesday, 10th inst., at Larbert, to consider their further action regarding the National Insurance Act. The meeting instructed the delegates who were appointed to attend the representative meeting of the Medical Association to vote in favour of giving service under the Act.

SMALL-POX IN GLASGOW.

Dr. A. K. Chalmers, the Medical Officer of Health for Glasgow, reported to the Health Committee that towards the end of the first week in December a case of small-pox occurred under circumstances which create some anxiety as to the immediate result. The

patient was one of the crew of a vessel which arrived at Rothsay Dock on the morning of December 4th from Seville, and has been taken to Crofthead Hospital. The patient's home was in Ayr, and he went home by train on the evening of the arrival of the vessel, and returned to his work on the vessel the following morning, December 5th. He remained at work during that and part of the following day, but feeling too ill to continue returned to Ayr on Friday, December 6th, where he consulted a doctor, and was discovered to be suffering from small-pox. On inquiry being set on foot, it was found that the patient had made three journeys between Glasgow and Ayr, travelling in a third-class compartment with other passengers, whom the Health Department are unable to trace. He visited at least three places of refreshment and one music hall, and must have been in close proximity to many people during the two days Thursday and Friday.

All the crew of the vessel were revaccinated, and the ship sailed last week for Cardiff. The known contacts are being kept under observation, and disinfection has been carried out of all places which the patient was known to have visited, but a considerable number of unknown persons must have been in contact with him at some stage of his movements, and it is with regard to those that most anxiety prevails.

BELFAST.

BELFAST DISTRICT LUNATIC ASYLUM.

THE annual report of the Inspector of Lunatics, Dr. T. J. Considine, on the condition of the Belfast Asylum has just been published, and is calculated to give much pleasure to all concerned, as the Inspector gives unstinted praise to the Villa Colony at Purdysburn, on which so much money has been spent during the last few years. There can be no question, he says, that for healthfulness and comfort the buildings and site at Purdysburn are unsurpassed by any public asylum in the United Kingdom, and this has been achieved at a very moderate cost owing to the energy and industry of the Committee of Management, whose untiring devotion to the welfare of the insane cannot be too highly spoken of. There are now about 400 patients in the new asylum, and about 800 in the old asylum in the city, and about 50 more in Ballymena Workhouse. The Inspector urges the hastening of building operations at Purdysburn so that more patients may be housed there, and this plea is earnestly seconded by the Resident Medical Superintendent, Dr. William Graham, whose aim is to transfer all patients eventually to the country asylum, and close the old city asylum entirely.

PUBLIC HEALTH.

Belfast is at present suffering from an outbreak of scarlatina and measles, with considerable mortality among children. The general death-rate has in consequence risen to 23.5. It is most satisfactory to note that typhoid is almost absent from the city. Some weeks lately no cases have been reported, and other weeks only one or two. A few years ago it was taken for granted that cases would occur by the score at this time of year.

MEDICAL STUDENTS AND THE UNION HOSPITAL.

The Infirmary Committee of the Belfast Guardians have been considering a request from the Belfast Medical Students' Association that a number of senior medical students should be admitted as resident pupils in the workhouse hospitals. A deputation attended from the Association to urge their request upon the Guardians. They pointed out that at present the yearly average number of students entering the Belfast Medical School is about 60. The Royal Victoria Hospital can take 32 resident students each year, and the Mater Hospital can take 16 for a period of three months each. The students pay the hospital authorities about 15s. per head per week for maintenance. Dr. Hall, on behalf of the visiting medical staff, said that the proposal had their full approval, and he believed that if it were granted it would tend to raise the standard of the training school for nurses, and would improve the status of the institution. The

Master said that he could provide accommodation for four students at a time, and it was ultimately resolved to inform the Local Government Board of the request, and ask whether such a scheme had been adopted by any other poor-law institution in Ireland, and whether the Board would be prepared to consider such a scheme for Belfast.

THE INSURANCE ACT.

A meeting of all the medical men in the Belfast district was convened on December 12th by the local division of the British Medical Association to consider the answer to be made to the Chancellor's latest proposals. The Chairman of the Division, Dr. Gardner Robb, presided, and made a short statement as to the present position, and called upon the secretary and representative of the Division, Dr. George Elliott, who made a further statement, and explained various points upon which members were not clear. The voting resulted in 164 being against accepting service under the conditions offered by the Chancellor, and 10 in favour of accepting. The Chairman made an urgent appeal for support to the Guarantee Fund, without which, he said, it was impossible to maintain the fight. Some members seemed to have an idea that the fund should depend upon the consultants and a few members who made big incomes, or at least whose incomes were derived from larger fees, but this was the general practitioners' own affair, and if they did not support the fund they need not expect others to do so.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

REFLEX STIMULATION OF THE VAGUS CENTRE IN THE TREATMENT OF DISEASE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read Dr. Brand's article in the MEDICAL PRESS AND CIRCULAR, December 11th, 1912, p. 631, with much interest. For many years I have paid attention to the subject of counter-irritation, and have a high opinion of its possibilities. As he points out, one of the great drawbacks to a more universal adoption of this method is the fact that no one has done the sort of scientific work that is so necessary nowadays before medical men will believe. The mere clinical observations of any worker, no matter how eminent he may be, are looked on with scepticism, and when they emanate from such an obscure person as myself they are scorned as unworthy of notice. My first contribution was a modest letter to the *British Medical Journal* about ten years ago. Two medical men took notice of it. One asked for more particulars, and by a modified plan has produced splendid results ever since at a well-known spa. The other wrote to the JOURNAL saying the treatment could be nothing more than palliative. I have been accused of undue optimism, claiming results unjustifiably, imperfect observation, and so on. Some have called me a quack, others have said the whole thing was due to suggestion, that the patients would have got well anyhow, and so on. The most serious setback I have received at all was at the hands of an eminent London practitioner, who said he had tested the methods I advocated, in a series of cases, and had convinced himself that they possessed no advantage over already well-tried procedures. He, as far as I know, has never published notes of these cases, nor would he send me any when requested to do so.

By chance I heard of one of his cases. The patient was treated by the method in question for one week only. It was then condemned as unsuitable. In my opinion no practitioner, however eminent, should conduct such observations until he has had a good training by someone experienced, and it would be better if the first few cases he attempted on his own account were supervised.

This may sound unreasonable, but I am now referring to spinal blistering as advocated by Dr. P. W.

Latham. In experienced hands this remedy does an immense amount of good in some of the most obstinate cases of arthritis, and also in certain cases of organic disease of the spinal cord. If conducted by a novice the patient may suffer unduly. I can quite believe that Dr. Brand has not yet heard of me or my doings, I would therefore ask him to kindly refer to my article in the *MEDICAL PRESS AND CIRCULAR*, May 8th, 1912. I feel sure he would be interested, as there is much in it that goes far towards supporting his own valuable work.

I am delighted that he has made these observations, as it will advance the cause of counter-irritation and will be a valuable addition to such an established fact that wherever hyperemia is produced antibodies are created of better quality and in greater quantity than before.

The theory that germs and toxins are extruded through raw surfaces in the skin, from deep parts of the system, is not generally believed, but I strongly support it myself.

I feel that the time is not far distant when counter-irritation and bleeding will be placed on a scientific footing by modern methods and be universally used in spite of the more dazzling vaccines, X-rays, salvarsan, etc.

I also heartily welcome Dr. Fieisch's remarks on bleeding. His plan will do much towards restoring this undoubtedly powerful remedy to popular favour. I have read this article carefully, but I failed to find any reference to Schroeder's work in which he claims to have proved that a series of small blood-lettings raise the body resistance to infection, and so promote general well being. See *B. M. J.*, Jan. 8th., 1910.

I congratulate you, Sir, on your acumen and broad-mindedness in publishing the articles in question, and feel grateful to you also.

I am, Sir, yours truly,
W. J. MIDELTON.

112, Charminster Road, Bournemouth.
December 14th, 1912.

TREATMENT BY COUNTER-IRRITATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was interested in Dr. Brand's article on stimulation of the vagus in treatment of vomiting and purging. I have not a *Medical Digest* by me, but I think if anyone looks up the subject he will see it discussed about 24 years ago. I fix the time thus: A charwoman who had been assisting while my servants were laid up with influenza in one of the early epidemics returned one night late bringing her child of a little over a year. It was collapsed with vomiting and purging, and my wife asked me to see to it. To her astonishment I proceeded to paint blistering fluid on a small space about the size of a shilling on the neck below the angle of the jaw, and she laughed at treating the neck instead of the abdomen. However, the child was brought next morning very much improved, and quite rallied. The small doses of calomel had probably something to do with the recovery. The treatment was not original on my part. I do not write this to in any way depreciate Dr. Brand's article. We ought to be obliged to him for advocating an old method of treatment, of which I have had frequent proof of the efficacy, as nowadays nothing is good unless new. I have not had any experience in treatment by this method in the other cases mentioned.

I am, Sir, yours truly,
JAMES HAMILTON, M.D.

60, Sydney Street,
Chelsea, S.W.
December 16, 1912.

University of Oxford.

At a Congregation held on December 14th the following degrees were conferred:—

D.M.—C. D. H. Corbett, University.
B.M.—H. T. Evans, Jesus; G. H. Varley, St. John's; G. Stanger, Lincoln; R. A. Fawcus, Oriel; E. Scott, St. John's; J. Sainsbury, Oriel.

REVIEWS OF BOOKS.

TUBERCULOSIS OF JOINTS. (a)

In the introduction to his monograph, Dr. Ely opines that the treatment of tuberculosis of joints in the present day is almost entirely empirical, as we have not sufficiently considered, or are ignorant of, many of the fundamental facts concerning joint lesions, as shown by the microscope and naked-eye specimens. We have tried to substitute clinical experience for exact knowledge. On this account the writer has dealt with the subject in some detail from the pathological point of view in the first forty pages of his work. He discusses at some length the joint tissues which are, and those which are not, attacked by the tubercle bacillus, the effects on them of abscess formation and mixed infection, and the histological changes brought about by the different methods of treatment. He bases his conclusions on the facts he has ascertained by a painstaking and systematic macroscopic and microscopic examination of a number of operation and museum specimens. According to him, conservative methods are the proper and rational treatment of joint tuberculosis in the young. In adults, when no improvement follows six months' treatment by rest, etc., the knife should be used, not with the idea of removing all diseased tissue, but to render the joint functionless, by bringing about bony ankylosis, if possible. Cure follows, because susceptible joint tissues are replaced by those in which tubercle cannot flourish, provided there is no secondary infection. As an example we quote from the latter half of the work, which deals systematically with the diseases of the spine and various joints. "Consequently, in our resections of tuberculous hips" (in adults), "we shall not attempt an impossible task" (*i.e.*, extensive and complete removal of tuberculous granulations), "but shall simply lay hold of the vital principle—dislocation." "We deprive the joint of function."

Dr. Ely's work is well and suitably illustrated with skiagrams, micro-photographs and other figures. The text is divided into two sections and an appendix. The first section, "Joint Tuberculosis in General," besides pathology, discusses symptomatology, diagnosis, and treatment. Section II. we have already referred to. The appendix contains some seventy clinical histories of patients, which include the laboratory notes on the diseased arthritic structures removed at operations. A great number show no tubercle in the diseased bone on microscopy; in the majority tubercles were found in the synovial membrane, and in a few no tubercles were found, although the condition was diagnosed clinically as tuberculosis.

Although some will not agree with the author's conclusions, this cannot seriously impair the value of Dr. Ely's work and records, which are a useful addition to the literature of the subject, and will repay the reader's careful perusal.

DISEASES OF THE NERVOUS SYSTEM. (a)

In this volume on Diseases of the Nervous System, the author has made a departure from convention, in that he has adopted, as far as is possible, a clinical rather than a gross anatomical classification of the diseases of which he treats. The usual arrangement of grouping together all lesions of the brain, or of the spinal cord, or of the peripheral nerves, is replaced by one which brings the symptoms of lesions of various systems of neurones into prominence, irrespective of whether the site of the lesion in the neurones be central or peripheral. Thus we find hemiplegia, monoplegia, primary lateral sclerosis, and disseminated sclerosis in consecutive chapters. Again, lesions of the cauda equina, multiple neuritis, and anterior poliomyelitis follow each other without any aggressive interruption. Whatever the neurologist who has already mastered the primary difficulties of dealing with his subject may think of this arrangement—he may (though we do not believe it) hold it to be un-

(a) "Joint Tuberculosis" By Leonard W. Ely, M.D., Orthopedist to the Children's Hospital, Denver, U.S.A. Royal 8vo., Pp. 241. Illustrations 72. Bristol: John Wright and Sons. 1911.

(a) "Diseases of the Nervous System." By Judson S. Bury, M.D., F.R.C.P. Manchester University Press. 1912.

scientific—there is no doubt that the student who is struggling with the elements of neurology will find it admirable. It not only enables him to remember the phenomena presented by the symptom-complexes which have arrived at the dignity of a name, but—and this is the important thing—it introduces him to the principles of topographical diagnosis on which he has to rely in every case for which a parallel cannot be found in his reading or previous experience. Moreover, it awakens him to the extreme interest of the diagnosis of a nervous disease which before seemed too complicated and terrible to face.

In the opening sections on anatomy and physiology the author has given in a brief space a very accurate and concise account of our present knowledge on these subjects. He has chosen well what to omit and what to retain. A knowledge of these early chapters will prevent difficulties in understanding symptoms which would otherwise arise when the phenomena of various diseases are being investigated. The accounts of the better known diseases—*e.g.*, locomotor ataxy and disseminated sclerosis—are well written and not burdened with too much theorising or the recital of rare complications. The book nowhere aims at being one of reference, but, none the less, it contains much valuable information on rarer conditions, and on the rarer manifestations of common conditions.

The sections dealing with tetany and chorea and with habit-spasms, tics and hysteria are all good, but we regret the author did not give an account of modern theories, especially modern French theories, regarding the origin of the so-called functional neuroses. These theories are, it is true, *sub judice*. They are quite possibly erroneous and are certainly inadequate, but they are extraordinarily interesting, and they enable one to form some rational conception of the proper status of those diseases which one hears too often referred to as "only a functional paralysis," or, "another of these hysterical cases." The addition of twenty, or even forty, pages on this subject would have enhanced the value of the book. After all, these affections are among those that can be cured!

The illustrations, whether diagrammatic or from photographs, are good, and are in keeping with the general good workmanship and judgment which the author has shown throughout the book.

SIR JOHN BURDON SANDERSON. (a)

It was right that the life of Sir John Burdon Sanderson should receive an adequate memoir. His widow entered on the task, but left it incomplete, and in finishing the work, Professor Haldane and his sister have performed not merely a pious duty to their family, but a public service which we gladly recognise. Moreover, the collaborators show a due sense of the fitting. The authors have written an adequate memoir of a distinguished man, while they have been careful that it should not be spoiled either by over-elaboration or by an attitude of uncritical admiration. If they have erred at all, it has been in the direction of brevity.

Burdon Sanderson came of a good Northumbrian stock, many of his relatives being distinguished in various branches of learning and activity. He was born in 1829, and in 1847 entered at Edinburgh University for the study of medicine. Even at that early date it was rather the attraction of the sciences cognate to medicine than the art of healing itself that directed him in his choice of a profession. At Edinburgh of his teachers he was perhaps in closest relation with Balfour, Goodsir, and Bennett, the last of whom was the first medical teacher in Great Britain to make systematic use of the microscope. On leaving Edinburgh, he spent some time in Paris, attending the lectures of Wurtz and Claude Bernard. One of his intimates in Paris was Dr. Pavy. In 1853 Sanderson settled in London, having been appointed Registrar of St.

Mary's. Three years later he became the first Medical Officer of Health for Paddington.

It is from this time that his scientific career really dates, though it was not until 1870 that he definitely abandoned his private practice, which had, indeed, never been large. Through these years, however, in addition to his work at Paddington and his hospital work at St. Mary's, the Middlesex, and Brompton Hospitals, he was constantly engaged in sanitary and physiological investigations. He conducted numerous inquiries at home and abroad on behalf of the Government, both in the field of veterinary and of human disease. His selection for such work came first from Dr. (afterward Sir John) Simon, Medical Officer to the Privy Council, who early recognised his abilities. In 1872 Sanderson was appointed Professor Superintendent of the Brown Institution, and thereafter devoted himself entirely to scientific work. His later career, first at University College and then at Oxford, is known to us all.

It is not necessary to attempt to settle Sanderson's place in the history of physiological science. Though no discovery of prime importance is assigned to him, he was essentially an original worker. He came just at a time when physiological science was beginning to be precise. He saw the need for getting away from the old generalities and untested hypotheses, and it is possible that he placed too much stress on precision of methods. "Science is measurement," he once said (though he afterwards modified it), and the phrase expresses both his strength and his limitations.

The half-dozen or so of Sanderson's papers and addresses included in this volume are admirably selected. All are of general interest and some of a special topical interest at present. His address on "Our Duty to the Consumptive Bread-earner," delivered in 1901, should be read by everyone concerned in the administration of the sanatorium benefit of the Insurance Act. Professor Schäfer's recent address should be read side by side with his former chief's presidential address to the British Association delivered in 1889. The older thinker is, at any rate, the more cautious.

LITERARY NOTES.

FROM John Wright and Sons, Ltd., Bristol, comes a handy and improved "Physicians' and Surgeons' and Consultants' Visiting List" for 1913, which has been compiled by Dr. Robert Simpson. This list economises space and the practitioner's time by enabling him to write his patient's name only once a month instead of weekly as heretofore. The book is well bound and of a convenient size, and the price varies from 5s. to 7s. 6d., according to the number of patients (40 to 240) for which it is ruled.

* * *

FOR the medical man who is interested in photography, one of the best books of the year is the "Wellcome" Photographic Exposure Record and Diary. This little book is one which justifies its annual arrival by its unmistakable utility. A panoramic view of all that is most practical and progressive in modern photographic processes is included in its contents, for every step in the production of effective prints, including exposure, focussing, development, the after-treatment of negatives, printing by all processes, toning, etc., is described fully, but with admirable conciseness. A novel feature this year is the article on the new method of obtaining blue and green prints by toning. Even the tyro should succeed in obtaining a high percentage of printable negatives by the use of the "Wellcome" Exposure Calculator. Three editions of the work are issued, namely, the "Wellcome" Exposure Record and Diary for the Northern Hemisphere and Tropics; for the Southern Hemisphere and Tropics and a special edition for the U.S.A. In ordering, care should be taken to specify which edition is required. The Northern Hemisphere edition is obtainable from all chemists and photographic dealers, etc., at the price of one shilling.

NEW PREPARATIONS.

PELLIDOL.

WE have received from Messrs. A. and M. Zimmermann samples of "Pellidol," which is chemically the diacetyl derivative of amidoazotoluol, having the distinct advantage over ordinary scarlet red in that it possesses no colouring properties, and any stain of the skin or linen can be removed by soap and water. We have been enabled to test its action in several cases of ulceration, in which it acted extremely well. In the form of a 2 per cent. ointment it is eminently suitable for use in ulcers of the leg as an epithelial regenerator. It is soluble in alcohol, ether, and also in vaseline, fatty substances and oils.

AZODOLEN.

IF "Pellidol" be mixed with equal parts of "Iodolen," itself a combination of the well-known antiseptic Iodol with albumen, containing about 30 per cent. of iodine, a yellowish powder results, which possesses no staining properties. This substance is known as "Azodolen," and this special combination of an epithelial stimulant with an antiseptic may well find a place in the treatment of those forms of ulceration where a syphilitic taint is suspected.

NOVATOPHAN.

FROM the same firm comes a specimen of an improved form of atophan (2-phenylchinolin 4-carbonic acid), for use in the treatment of gout. The new substance is the ethylester of methylated atophan, which, according to Dr. Bendix, is equivalent to the latter in clinical effect and in action. It has the distinct advantage, however, of being tasteless, so that it may be administered to patients with the most sensitive palate. It is an almost colourless preparation, insoluble in water, and it may be given in precisely the same dose and manner as atophan in all forms of diseases due to faulty uric acid metabolism. The tablets, 6 to 10 daily, should be allowed to disintegrate in water and swallowed, followed by more water.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons of England.

AT their meeting on Thursday, December 12th, the Council considered a report from the Board of Examiners in Anatomy and Physiology for the Fellowship in reference to the physiological part of the examination, and also a memorandum from a number of teachers on the same subject. The report was referred to a Committee of the Council for consideration. The Board of Examiners state, (a) that, in consideration of the large scope of the subject matter in physiology, the Examiners feel that the knowledge of candidates would be more fairly tested, if a choice of questions were permitted in the written examination in physiology; (b) that, if such a choice be approved, then the Examiners suggest that the number of questions in the written paper in physiology should be increased to eight, and the paper divided into two parts, each part containing four questions, of which a candidate must answer only two. The candidate would thus, as now, answer four questions, and the time of the whole paper would be, as at present, three hours; and (c) that, if such choice is offered, it will be necessary to inform the Examiners conducting the oral part of the examination in physiology what questions in the written paper have been answered by the candidate.

On the recommendation of the Board of Examiners in Dental Surgery the recognition of the London Hospital Dental College was confirmed. The Council also decided to add Radley College and the King Edward School, Lytham, to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics, and the course of laboratory instruction in Public Health at the Uni-

versity of Cambridge to the laboratory course recognised by the Royal Colleges of Physicians and Surgeons for their Diploma in Public Health.

At an ordinary meeting of the Council of the Royal College of Surgeons held on December 11th, with Sir Rickman J. Godlee, president, in the chair, the following members of the College were admitted Fellows:—

E. C. Alles, L.R.C.P.Lond., L.M.S.Ceylon, H. L. Attwater, M.A., M.B.Camb., L.R.C.P.Lond., L. Bromley, B.A., M.B.Camb., L.R.C.P.Lond., Ibrahim Fahmy-el-Minyawi, L.R.C.P.Lond., A. R. Finn, M.D.Lond., A. D. Gardner, B.A., M.B.Oxon., W. Gilliatt, M.D.Lond., E. L. Pearce Gould, M.A., M.B.Oxon, W. P. Gowland, M.D.Lond., S. L. Graham, M.B.Lond., T. T. Higgins, M.B.Manch., G. Ley, L.R.C.P.Lond., E. C. Lindsay, M.B.Lond., C. Mackenzie, M.A.Camb., L.R.C.P.Lond., A. C. Morson, L.R.C.P.Lond., A. B. O'Brien, M.D.Lond., R. Pearce, L.R.C.P., H. Platt, M.B.Lond., S. H. Rouquette, B.A.Camb., L.R.C.P.Lond., J. G. Saner, B.A.Camb., L.R.C.P.Lond., W. H. Trethowan, M.B.Lond., W. Smith, L.R.C.P.Lond., R. M. Vick, L.R.C.P.Camb., G. Viner, M.D.Lond., J. O. D. Wade, M.B.Lond., W. S. Wildman, L.R.C.P.Lond., I. S. Wilson, M.D. New Zealand.

The following candidates, not being members of the College, were also admitted Fellows:—

D. W. Hewitt, Staff Surgeon, R.N., M.B. R. Univ. of Ireland, K. Mackenzie, M.D.Edin., L. E. B. Ward, M.B., F.R.C.S.Edin.

LICENTIATES IN DENTAL SURGERY.

The following candidates were admitted Licentiates in Dental Surgery:—

C. A. Ascher, M. Ade, W. Adderley and D. H. Barr, D. C. Bernstein, C. C. Blundell, C. W. Bond, R. L. Booth, R. Boutwood, A. D. Buck, H. O'N. Butler, R. Campbell, C. H. Child, T. P. Cooper, W. H. Dye, P. L. Ealand, L. E. Forster, R. Fox, W. F. Gawne, J. W. Gilbert, L. P. Harris, W. A. S. Hills, H. Holburn, A. M. Hughes, A. A. Hume, H. Humphrey, G. G. Jack, W. H. Keay, R. C. Kershaw, T. C. Kidner, R. M. King, F. W. Lawrence, A. Lawrey, E. McArd, J. W. Mayer, H. B. Neely, C. J. O'Callaghan, C. V. Osborne, Lily F. Pain, W. Parry, W. L. Partidge, H. J. Pegler, C. J. Phillips, H. E. C. Rose, M. Schneider, A. D. E. Shefford, W. J. Singleton, F. J. Smith, P. J. Wakley, J. J. Ward, S. J. F. Webb.

Bequest to Dublin University and Royal College of Surgeons, Dublin.

MR. ROBERT JOHN MONTGOMERY, F.R.C.S.I., M.A., M.B., of 4, Gardiner's Row, Dublin, member of the British Medical Association, and Dublin Ophthalmic Club, who died on July 7th last, left personal estate valued at £4,823 17s. 6d. Probate of his will, dated July 7th last, has been granted to his sisters, the Misses Fanny, Louisa Mary, and Edith Florence Montgomery, all of 4, Gardiner's Row. The testator left £5,000 to the Boards of the Dublin University and the Royal College of Surgeons, Ireland, for a "Mary Louisa Montgomery Lectureship" in Ophthalmology, to be held alternately by the said Boards for a period of five years, the lectureship for the first five years after his death being held by Dublin University. Should the income of his sisters, apart from that from real estate, amount to less than £200 per annum, then it shall be made up to that amount from the said fund, and the ultimate residue of his estate he left to his sisters in equal shares.

Medical Matters in Parliament—The Medical Acts.

SIR PHILIP MAGNUS moved a clause preventing the Irish Parliament from dealing with the Medical Acts of 1858 and 1886, and the Dental Act of 1878. His main object was to maintain the powers of the General Medical Council, especially in regard to examinations, the aim being to establish uniformity of qualification in both countries.—Mr. Birrell could not agree with the new clause. The medical profession in Ireland could very well look after itself, and it need not be feared that it would act in a retrograde manner.

The clause was defeated by 281 to 106—Government majority, 175.

Conviction of Bogus Practitioners.

ON the 6th inst., at the Munster Assizes at Cork, before Mr. Justice Dodd, Patrick H. O'Shea, *alias* R. H. Graham or Graham Shee, H. Ellison and Michael Browne, were put forward (from County Tipperary, S.R.) and pleaded not guilty to the charge that they did conspire to cheat and defraud by false representations, etc., and did also obtain money by false representations on different days in different months in the present year.

Mr. M'Sweeney said the form of cheating was that the prisoners pretended to be qualified medical men and qualified dentists, and specialists in the treatment of disease, and by that means they obtained large sums. Quacks were entitled to practise so long as they practised as quacks. A quack could not hold himself out to the public as a qualified medical man. The conspiracy took place in the county of Tipperary, and the prisoners roamed all over the county, and the money they obtained was from poor farmers and others. When Ellison was arrested a number of letters were found in his possession. There was one letter written by O'Shea, a billiard-marker from Waterford, to Ellison, who was then in London. It stated:—"I have just returned from Tipperary and received several letters. . . . I have made all ready for you and have engaged apartments, and men are already at work with the scheme. . . . I believe I said in a previous letter that, like yourself, I am not fully qualified." He was not qualified—he was a billiard-marker from the Co. of Waterford. A series of letters passed, and ultimately, on July 13th in the present year, Ellison, whose address was 219 St. John's Road, Clerkenwell, arrived in Tipperary. He was originally a medical student—a chronic medical student, and when the police were first able to trace him in London he was in the employment of a man named Vine. When he arrived in Tipperary he had a card: "Henry Ellison, M.R.C.S., L.R.C.P." "This job will break up at any moment. . . . Write by return and carefully seal letter. I will try and pack up in a week's time and keep my fare and hook it, as this is a fraud," Ellison wrote to his wife; "it is nothing but a swindling game. I have about fifty cases to serve; I do all the work and get sixpences and bobs—about two shillings, I can't afford boots. . . . I leave here on Thursday next." The prisoners settled down in a public-house in Hollyford, in Tipperary. A series of cards were issued, and Mr. Shea, billiard-marker, became "Dr. R. H. Graham, Specialist in Dentistry. Painless extraction. Moderate prices." He appeared in another part as "Dr. R. H. Graham, Philadelphia Medical Institute." There was also another card: "Dr. Ellison, Specialist in the treatment of consumption, rheumatism, sciatica, wasting diseases." There was also an announcement of the "most wonderful discovery of the age for the treatment of sciatica, rheumatism and paralysis by hypodermic injections into the parts affected." Counsel said that beyond all doubt Browne knew about the swindle. He was hired by these people. This form of swindling was a danger to the public, and it could not be tolerated that billiard-markers and drapers' assistants should go about the country practising medicine.

Evidence was given in support of counsel's statement, and the jury returned a verdict of guilty against the three prisoners on the count of conspiracy to obtain sums of money by false pretences; they strongly recommended Browne and Ellison to mercy.

The prisoners were put back for sentence.

Longford Doctor's Sad End.

WIDESPREAD regret was caused in Longford by the sudden death on Sunday morning of Dr. Fredrick J. Myles, who was found that morning by his house-keeper lying dead on the floor of his bedroom. An inquest was held on Monday by Dr. V. Delany, Coroner for South Longford, when Dr. McCann stated that he was called in on Sunday morning and found Dr. Myles lying on his face on the floor of his bedroom. His nose was broken and there was an abrasion on the forehead, and, from all he observed, he believed that deceased, feeling ill when getting out of

bed, had some sort of seizure and, having fallen on his face on the floor, death was caused by suffocation. The jury found that death was caused by suffocation, in accordance with the medical testimony, and added a rider expressing sympathy with the relatives of the deceased.

Libel Action by Irish Medical Man.

LAST week, at Nisi Prius, Dublin, before the Lord Chief Baron and a city special jury, the hearing was resumed of the libel action in which Dr. Thos. Higgins is plaintiff, and Mr. Denis Shaughnessy, Co.-C., defendant. The alleged libels complained of are contained in a letter, alleged to have been written to the Athy Board of Guardians, complaining of the condition of the doctor's dispensary at Stradbally, charging him with receiving money from medical relief patients whom he was bound to attend free, and suggesting that medicine bottles supplied by the Board of Guardians were appropriated by the doctor to his own use.

After several days' hearing, the following questions were submitted to the jury and answered as mentioned:—

"(1) Did paragraph (a) of the letter mean that the plaintiff had been guilty of grave irregularities and serious violation of duty as medical officer?—Yes.

"(2) Did it mean that as such medical officer he made use of his position to extract fees to which he was not entitled?—Yes.

"(3) Did it mean that as a physician and surgeon he is unfit to be retained by the Board of Guardians of the Athy district as medical officer of the Stradbally Dispensary District?—No answer.

"(4) Did the second paragraph (b) mean that the plaintiff was habitually guilty of violation of his duty as medical officer of the dispensary in refusing to supply bottles to dispensary patients entitled to free medicine, or compelling or requiring them to supply bottles at their own expense, although the plaintiff is supplied with bottles by the Guardians for the purpose of dispensing medicine?—Yes.

"(5) Did Mrs. Stone make the statements to the defendant mentioned in the portion of the letter of April 10th (marked a) from 'I issued visiting tickets,' to 'bottle every time'?—Yes.

"(6) Did the defendant honestly believe the said statements, and did he communicate said statements to the Guardians of the Athy Union in the *bonâ fide* discharge of his duty as warden and ratepayer, and in the belief that same were true and without malice?—The defendant honestly believed the said statements and ratepayer in the belief that same were true, but Union in the *bonâ fide* discharge of his duty as warden and ratepayer in the belief that some were true, but with malice on both sides.

"(7) If you answer 5 or 6 in the negative, assess the plaintiff's damages?—One farthing."

Upon these findings the jury found for the plaintiff with one farthing damages. The judge gave judgment for the plaintiff for one farthing, together with a further sum of one farthing for costs.

Royal College of Surgeons of Edinburgh—The Fellowship.

At a meeting of the College held on Thursday last, December 12th, the following gentlemen, having passed the requisite examinations, on October 11th, last, were admitted Fellows:—

William Anderson, M.B., Ch.B., Fredk. A. F. Barnardo, M.B., Ch.B., Walter Waddell Carlow, M.B., Ch.B., Robert McLean Gibson, M.B., C.M., M.D., Wm. C. Grosvenor, M.B., C.M., M.D., Henry Fleming Hamilton, M.B., Ch.B., John William Hitchcock, L.R.C.S.E. (Triple Qual.), John Albert Lee, M.D., C.M., James Herbert Graham Robertson, M.B., Ch.B., Stanley Robson, M.B., Ch.B., M.D., C.M., Percy Alexander Ross, M.R.C.S.Eng., L.R.C.P.Lond., David Henry Russell, M.B., Ch.B., Norman Craig Shierlaw, L.R.C.S.E. (Triple Qual.), John Edward Llewellyn Simcox, M.B., Ch.B., William Percy Walker, M.R.C.S.Eng., L.R.C.P.Lond., D.P.H., and at the same meeting Arthur Robinson, M.D., Professor of Anatomy, University of Edinburgh, was admitted to the Fellowship.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

A GRADUATE (Glasgow).—The latest official return of the population of your city is 785,600. The average death-rate from all causes during November was 18.1 per week.

LECTURES ON EUGENICS.

A COURSE of six lectures will be delivered at University College by Professor Karl Pearson, F.R.S. (Galton Professor of Eugenics), Miss Ethel M. Elderton, Dr. David Heron, and Mr. W. Palin Elderton, on Tuesday evenings at 8 p.m., beginning on February 11. They will deal with the following subjects:—Heredity, Environment, and Parental Habits in their Relation to Infant Welfare; Heredity of Piebaldism and of Albinism in Man; the Relation of Fertility in Man to Social Value in the Parent; Some Points with regard to our Present Knowledge of Heredity in cases of Feeble-mindedness; the Mortality of the Phtisical under Sanatorium and Tuberculin Treatments; and Recent Studies of Heredity in Dogs, and their Bearing on Heredity in Man.

The course will be open to the public without fee, but applications for tickets should be addressed to the Secretary of University College.

LOCUM TENENS (Liverpool).—The ointment referred to is composed entirely of the hard and soft paraffins, coloured and perfumed to disguise its composition. The 2s. 6d. demanded for it is, of course preposterous, as its outside cost would be less than one penny.

INDIAN MEDICAL SERVICE.

THE Government of India has sanctioned the introduction of "Organisation, Administration, and Equipment" as a subject in the examination of lieutenants of the Indian Medical Service for promotion to the rank of captain. This sanction will have effect from January 1st, 1914, to embrace all lieutenants whose commissions are dated January 28th, 1911, and those of any earlier batch who have not by that date completed their departmental examination for promotion. It has also been decided that lieutenants of the Indian Medical Service may be allowed to appear for their promotion examination on completion of one year's service.

PATER (Leeds).—The Livingstone College, situate at Leyton, Essex, prepares and sends out Medical Missionaries to the Tropics. Dr. Harford is the Principal, and it would be advisable to communicate with that gentleman regarding your son. Much valuable work has been accomplished, and students of the College are held in high esteem.

ST. BARTHOLOMEW'S HOSPITAL.

WE are asked by the treasurer of St. Bartholomew's Hospital, Lord Sandhurst, to state that the generous response to the appeal to supplement the income of, and to extinguish a capital debt upon that institution, has averted the necessity of any immediate curtailment of the work of the hospital.

Further contributions are still required, but, in view of the help and encouragement received on all sides, it is hoped that the balance still required will be subscribed by the end of the present year, and our readers and especially the citizens of London are asked to give their aid to the attainment of this result. Subscriptions or donations may be sent to the treasurer at the Hospital, or to the Right Hon. the Lord Mayor at the Mansion House, and will be gratefully received and acknowledged.

DR. F. S. (Yorks).—The fact of the absence of Altmann's granules from the colla of practically all cancerous growths affords a valuable microscopic test for the presence of malignant disease when it is possible to remove portions of the growth for examination.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, DECEMBER 18TH.

ROYAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.).—8 p.m.: Mr. F. Enock.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics—2 p.m.: Thorst Operations (Mr. Gillies). 2.30 p.m.: Children's Out-patient (Dr. T. R. Whigham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P.

Brooks). 3 p.m.: X-Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 p.m.: Eye Operations (Mr. Brooks).

THURSDAY, DECEMBER 19TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1 Wimpole Street, W.).—5 p.m.: Cases by Dr. Pringle and others. NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynecological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture-Demonstration: Dr. G. G. Macdonald: Tuberculosis.

FRIDAY, DECEMBER 20TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF ELECTRO-THERAPEUTICS) (1 Wimpole Street, W.).—8.30 p.m.: At the Middlesex Hospital, W. Short Papers will be read and Cases shown.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Dr. A. Castellani (Colombo).

Appointments.

FRESHWATER, DOUGLAS H., B.C., M.D.Cantab., Physician to the Western Skin Hospital.

HASLAM, IVY E., M.D., B.S.Lond., M.R.C.P.Lond., Honorary Pathologist to the Warneford General Hospital, Leamington. KERR, HAROLD, M.D., Ch.B.Edin., D.P.H., Medical Officer of Health of Newcastle.

LUND, HERBERT, M.B., B.C.Cantab., F.R.C.S.Eng., one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 8 (Salford).

Vacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Anstruther (Fife), Athy (Co. Kildare), Medbourne (Leicester), Widnes (Lancs.).

Wrexham Infirmary.—House Surgeon. Salary £120 per annum, with board, lodging and washing. Applications to Secretary, Frank Sisson, Esq., 7 Hill Street, Wrexham.

Somerset and Bath Asylum, Wells.—Second Assistant Medical Officer. Salary £135 per annum, with board, lodging, washing, and attendance. Applications to the Superintendent.

Laboratories of Pathology and Public Health.—Fourth Assistant Pathologist. Salary £170 per annum. Applications to the Secretary, Laboratories of Pathology and Public Health, 35 New Cavendish Street, W.

Hereford County and City Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, washing, etc. Applications to the Medical Superintendent, Asylum, Burghill, Hereford.

Durham County Asylum.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging, laundry, and attendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.

Islands of Luig and Shuna, Argyllshire.—Medical Officer. Salary £150 per annum. Applications to G. A. Maclean Buckley, The Hall, Worth, Sussex.

Lancashire County Council.—Tuberculosis Officer. Salary £500 per annum. Applications to County Medical Officer of Health, County Offices, Preston.

Births.

BIRKETT.—On Dec. 13th, at Ortakey, Southsea, the wife of E. J. D. Birkett, M.D., of a son.

HAIR.—On Dec. 16th, at Wanlock, 31 Lampton Road, Hounslow, Middlesex, Jane, the wife of Allan Hair, M.R.C.S., of a daughter.

MAXWELL.—On Nov. 29th, at 29 Dowsett Avenue, Southend-on-Sea, the wife of Dr. James B. Maxwell, of a daughter.

THURLOW.—On Dec. 12th, at "Easdale," Frant Road, Tunbridge Wells, to Dr. and Mrs. Basil Lyons Thurlow—a son.

Marriages.

DICK—BRISCOE.—On Dec. 10th, at St. Michael's, Blackheath, Frederick Adolph Dick, M.B., B.S., second son of the late George Alexander Dick, and Mrs. Dick, of Blackheath, to Elizabeth, youngest daughter of the late Thomas Paul Briscoe and Mrs. Briscoe, of Blackheath.

MITCHELL—MASON.—On Dec. 12th, at Christ Church, Morning-side, Edinburgh, Major Arthur Henry McNeill Mitchell, R.A.M.C., Netley, elder son of the late Robert W. S. Mitchell, Esq., O.M.G., I.S.O., Emigration Agent, Calcutta, to Mary Stuart, younger daughter of the late J. Gordon Mason, Esq., Solicitor Supreme Courts, Edinburgh, and of Mrs. Gordon Mason, 1 Morningside Place.

Deaths.

BARTHOLOMEW.—On Dec. 10th, at 31 West Hill, Wandsworth, Alfred Aldam Bartholomew, L.R.C.P. and L.R.C.S.Edin., L.D.S., R.C.S.Edin., aged 52. R.I.P.

COBOLD.—On Dec. 11th, at the Elms, Bathaston, Bath, after long illness bravely borne, following appendicitis, Hugh Spencer Cobbold, only and much-loved son of C. Spencer Cobbold, M.D., in his 20th year.

WILLIAMS.—On Dec. 15th, at 2 Upper Brook Street, W., Charles Theodore Williams, M.D., M.V.O., F.R.C.P., Hon. Fellow of Pembroke College, Oxford, aged 74.

WINTOR.—On Dec. 14th, at Colchester, Katy, dearly-loved wife of Lt.-Col. T. B. Wintor, R.A.M.C., Military Hospital, Colchester.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX."

VOL. CXLV.

WEDNESDAY, DECEMBER 25, 1912.

No. 26.

NOTES AND COMMENTS.

The Great Refusal.

THE medical profession has stuck manfully to its guns, and at last Saturday's momentous meeting of the representative body of the British Medical Association the following resolution was carried by an overwhelming majority amid scenes of the wildest enthusiasm:—"That this representative body reject the proposals of the Government and adhere to the previous decision to decline service under the Act." The meeting had previously adopted a resolution to the effect that the latest regulations and the conditions of service are "in the best interests of the public and the profession, unworkable and derogatory." The public first, be it noted. Mr. Lloyd George's great scheme, beneficent as it might have been had the medical provisions been wisely and practically considered, now crumbles to dust like the Dead Sea apple. In spite of the few dissentients who have elected to cast themselves under the wheels of this Juggernaut Act, it is in the highest degree improbable, or rather it is impossible, that the medical benefits can now be administered as originally intended by the framers of the Act. The solidarity of the representatives of the Association is such that a resolution was also adopted that whatever the decision of the meeting, the minority agreed to acquiesce in the finding of the majority. These decisions come as an effective and crushing response from the medical profession which has slowly been awakening and now has at last arisen, giant-like, and conscious of its strength. This power, thus collectively asserted, must now be organised at once to form a Public Medical Service under its own control.

A Diploma in Psychological Medicine. THE demand for a one-portal system has been before the medical profession for many years, but, nevertheless, the creation of new qualifications goes on apace. Of

late years various Universities have come upon the scene and have contributed to the number of qualifying corporations. Within the experience of the present generation a diploma of public health has been obtainable at many of them, and it has been adopted almost without exception as a necessary condition of holding a public health appointment. A diploma of tropical medicine and another of ophthalmology have recently been created, and this is now followed by a diploma in psychological medicine, granted by the University of Cambridge. Medical men of two years' standing, who have had special clinical experience of insanity, are admitted to the examinations. The latter are divided into two parts, the first dealing with the anatomy and physiology of the nervous system, and a practical and oral examination in psychology. The second part embraces neurology, psychiatry, lunacy law and asylum administration. The examination will

be held in June or July of each year, and there will be a fee of six guineas for each part.

A Cambridge View.

THE specialisation of various branches of medical science obviously leads to an accumulation of technical knowledge of a high order. In some cases the student is unable to gain an adequate grasp of a given subject, owing to his want of training in subsidiary studies. To remedy that state of affairs is, above all things, the function of a university, or, for that matter, of any organisation that aims at a systematic scientific education. Clearly the proper time for the alienist to acquire a sound knowledge of psychiatry and neurology is before he assumes the varied and exacting duties of asylum work. There is much, then, to be said in favour of the view of the Cambridge authorities that an examination in psychological medicine and its cognate subjects, if established, could not fail to raise the present standard of efficiency in applicants for asylum posts, and that it would lead to the provision of appropriate courses for the training of those who wish to advance our knowledge of psychiatry. They believe that the legislature would quickly come to recognise the diploma as a qualification which must necessarily be held by all medical officers of public institutions for the insane, and as desirable for public medical officers of education, Poor-law, prisons, and so on. Any of our readers requiring further information should communicate with Dr. C. S. Myers, the Psychological Laboratory, Cambridge.

Sweated Medical Officials.

AT the present crisis in medical affairs, it is interesting to note that, in its dealings with our profession, the State has always obtained as much as possible in return for little or nothing. The gratuitous death certificate affords an apt example, and an even more contemptible one is the gratis birth certificate instituted by Mr. John Burns, under stringent penalty. Why should not a parsimonious administration, anxious to obtain necessary service at other people's expense, demand services of an equivalent kind from the lawyers? Then, again, the pay for many Poor-law appointments is scandalously inadequate, and it is only of late years that Government has interfered to protect its medical officers. There could be no more flagrant instance of petty injustice than that which forbids Poor-law medical officers from receiving fees for giving evidence in coroners' and other courts. The object is clearly to save the ratepayers' money at the cost of the sweated medical official. What guardian, we wonder, would forego his fees if called upon to appear as a witness in a workhouse case? Many other instances of Government "sweating"—there is no other word in the English language that conveys our precise meaning more crisply—might be cited, but there is no need to enumerate

grievances that are written indelibly in the history of medicine in the United Kingdom.

UNDER a somewhat different category falls an official complaint made to Mr. John Burns, President of the Local Government Board, by the official vaccinators. Their complaint is one of seriously reduced income. Under the old Act of 1898 exemptions were granted only on the signature of two magistrates, but under the Act of 1907 all that was altered, and now an applicant has merely to ask for and obtain an exemption from a magistrate. The results of this increased facility are striking. In 1906, before the new Act, the total exemptions were 53,828, in 1910 it had risen to 230,947, and in the first half of 1911 to 119,335. Since every such exemption means a loss to the vaccination officer, it is clear that the total reduction of his income must be considerable. When questioned in the House, Mr. Burns replied that out of 1,420 vaccination officers 487 have, it is alleged, suffered loss, but the case has been met by the payment of a gratuity by their boards of guardians. To this the Vaccination Officers' Association reply that they have investigated thirty cases where gratuities had been granted, and find they amounted to £513 18s. 2d., against a gross loss of £1,988 18s. 8d. If vaccination be necessary for the nation, this is bad news. Mr. John Burns has never shown himself a friend either of compulsory vaccination or of the medical profession. Now that the Government has fallen out with the doctors, the intervention of the ancient god Nemesis may be awaited with some amount of interest and curiosity.

LEADING ARTICLES.

SMALL HOSPITALS AND THE INSURANCE ACT.

THE future of the voluntary medical charities under the operations of the National Insurance Act presents a problem of considerable importance to various interests. It must be at once recognised that the Act provides with medical service and physic a vast number of persons of the class who have hitherto been accustomed to resort to the hospital for assistance of that kind. As a portion of the premium is paid by the insured persons, it is hardly likely that they will in future accept as a charity that which they are entitled to demand as a right. According to Mr. Lloyd George, those who need specially skilled advice will continue to visit the hospitals. Last week, in reply to a deputation of the chairmen of some of the larger London hospitals with attached medical schools, he made certain statements that deserve close attention. He contended that the main work of the hospitals is untouched by the Act, as medical men attending the insured do not cover the same kind of treatment as that of a hospital. Insured persons would still require hospital in-treatment and, to a less extent, out-treatment, and the claims of the charities upon private benevolence would continue the same. The Government had left the hospitals out of the scheme rather than imperil their voluntary nature, as any subsidy from public funds would be followed by public control. He further contended that the Act would ease the finances of the

hospitals by relieving them of a number of out-patients, and of those in-patients who, from sheer poverty, were unable to have home treatment. Then came the sting of the speech of the Chancellor of the Exchequer. He remarked that if there were any trouble it would be because some extremists wish to boycott or, at least, to differentiate against insured persons. According to his view, the perils underlying any such policy were three: first, the hospitals in many cases were chartered institutions, and such charters were open to revision; secondly, public generosity would be checked if any case of neglect were proved; and, thirdly, hospitals were under Royal patronage and assistance, which could not be engaged in acute controversy with the wage-earning classes. As regards the threat thus implicitly stated, it is likely to be absolutely futile so far as ninety-nine out of every hundred members of the honorary staffs of hospitals who have signed a pledge not to attend insured persons under the Act under existing conditions. Mr. Lloyd George will find the hospital question is not to be swept curtly aside, any more than the general practitioner is to be dragooned, bribed, bamboozled and ignored at the whim of an astute politician. It is safe to say that the loss of hospital charities, of eleemosynary gifts and of Royal patronage, even supposing any or all of these things were to follow a combined hospital protest against injustice, would not for a moment cause a single consultant or specialist to waver. Did Mr. Lloyd George realise the common social influence of the medical profession he would probably become more sparing of his stage thunder. How can he justify the handing over to unpaid consultants a considerable proportion of the vast burden of insured persons for whose sick treatment the State has become responsible? There is another aspect of the case which has a profound bearing upon the interests of the community. The large hospitals only were represented in the deputation to the Chancellor. What about the small and special hospitals? It is to the special hospitals that we owe a great, if not the greater, part of our advances in medical science. Many of these special hospitals existed long before there were any special departments attached to the large general hospitals. Are these small hospitals, with their fine traditions, with their organised special work, with their accumulation of experience, and in some instances with finely equipped laboratories, to be swept out of existence for the paltry reasons assigned by the Chancellor of the Exchequer? If so, their loss to scientific medicine and to the service of the public would be heavy and irretrievable. Of late years the medical charities of the Kingdom generally have come more or less under the control of certain large distributing agencies or Funds. In London the policy of these directing agencies has been that of open and avowed hostility to the small hospitals. The professional philanthropists who practically control the Funds have nothing to gain from the smaller

institutions, whereas the larger ones connote social prominence, titles, and the direction of enormous financial interests. It is to be hoped, however, that the State will not drift into the fatal blunder of permitting the special hospitals of the United Kingdom to be starved out of existence. A statesman of the calibre of Mr. Lloyd George would act more worthily were he to address himself seriously to the task of readjusting the relations of the hospitals, small and large, to the fresh conditions imposed by his all-perlexing Act. The wiser plan would be at any cost to endow all hospitals, large or small, and if necessary to accompany the gift with certain conditions that would neither degrade nor unnecessarily hamper the service of the medical profession. The fallacy of gratuitous service hangs like a millstone round the neck of the honorary staff of the voluntary medical charities. The system is rotten to the core, and were it to be swept away in the case of the hospitals, as it has been in the case of Parliament, the medical world would be well rid of a burden that is often bitter, and always economically unsound.

CURRENT TOPICS.

Christmas Fare and Health.

At this season of the year when jollity and good fellowship seize the reins and guide the social chariot out of the ruts of work and formality into the smoother ways of leisure and ease, one cannot help wondering how the national health will be affected as a result of the enriched diet consumed by all classes. It is no exaggeration to say that millions of people, even the poorest, will partake of what is to many the crowning meal of the year, the Christmas dinner. Turkey, roast beef, plum-pudding and mince-pies are not likely to be superseded as seasonable foods, and when these articles are more than duplicated, as they are in many households, the Christmas feast is repeated and kept up in a modified degree, for the best part of the week. Except in the case of the very poor this surfeit of rich diet, especially in carbohydrates, might be expected to bring some extra work to medical practitioners, and yet the records of men in busy general practice show little if any increase from this cause. This would indicate that greater temperance in eating, as in drinking, is becoming more universal. As a matter of fact, much greater time is allowed than usual for the digestion of Noël fare, for people have not to rush away from the table to catch trains. It is this atmosphere of calm and enjoyment, combined with the all-pervading sense of good cheer, that goes to make Christmas a healthy season rather than the reverse.

The Asylums Board and Medical Education.

At the last meeting of the Asylums Board an interesting report from a Sub-Committee was presented on the part the Board has long taken in medical education in London, and a claim was made for representation, in connection with other public authorities, on the governing body of the University of London. The report points out that classes have been established in the Board's hospitals for the clinical instruction of students, and a certificated course of study in a fever

hospital has been made part of the five years' curriculum of every medical student entering the profession. Over 6,500 students have completed the course in the Board's hospitals. Facilities have also been provided by the Board for the study of smallpox by medical men and medical students when a sufficient number of cases of that disease has been under treatment in their hospitals. In addition they have, within the past few years, instituted classes for the instruction in hospital administration of qualified men who are desirous of taking the Diploma in Public Health. In connection with research work it has been resolved to appoint a research bacteriologist. The Board has resolved to request the Royal Commission on University Education in London to consider the question of recommending that the Board should be given representation on the Senate of London University.

The Scarlet Woman.

THE British Committee of the International Abolitionist Federation has just published its correspondence with the India Office on "Our Army in India and Regulation of Vice," in which the Government is accused of granting official recognition to prostitution, and thereby encouraging vice. It appears that in many cantonments the periodical examination of women has been permitted, and that brothels for the use of soldiers are not only permitted in cantonments, but are placed under some sort of medical control. The committee holds that there are two main grounds for objection to the system—one that a class of women are placed outside the law, treated as suspects, and differentiated from the men who are necessarily their accomplices in the conduct concerned; and, secondly, that the system affords a positive encouragement to vice by giving it Government recognition and protection. The whole question is a very vexed one. The Army wants an efficient fighting machine. It finds that its men can resist everything except temptation, and that they are specially prone to succumb to feminine seduction. It finds that this weakness of the soldier, which it cannot prevent, is the direct cause of a great deal of sickness and inefficiency, and accordingly takes effective steps to prevent this. That these measures may inflict hardship on the harlot is beside the point. She knows that infection means expulsion from the cantonment, and that this is part of her ordinary trade risks. If we can omit the purely moral point of view the Army's action is logical and laudable. But the moralist is not to be denied. He lays down that prostitution is unnecessary and disgraceful, and that for a Government to recognise its existence and lessen its risks is subversive of all morals. As a mere matter of history, however, the harlot has flourished in spite of all the repressive measures that have at one time or another been enforced against her. The prostitute is certainly a problem, but removing some of the risks of her calling is not likely to increase her *clientèle*—and it will undoubtedly lessen the amount of pain, suffering and deformity which are now the lot of her accomplices. One cannot deny, however, that official control implies, if tacitly, official sanction.

Simplex Munditiis.

ST. PAUL exhorted us to do everything decently and in order, and ever since then women have been tidying our desks. We leave our papers, pens, and hypodermic needles lying about where we can get them in a picturesque seeming confusion, whose

chief beauty lies in its unstudied practicability. We really know where things are when we want them, although it would admittedly be far from easy to describe their exact location to the casual outsider. Then, one day, when we are a "prey to hastening ills" and want something quickly, we find our precious possessions have been "tidied." Parallelism tempered with symmetry is pathognomonic of the feminine touch. The edges of everything must be parallel with the edges of everything else, and neat pyramids are formed by the simple process of putting everything on something bigger. This craze for the rectangular parallelogram is one of our essential human characteristics. It is intensely finite. The paths of the planets are awful curves, but a dropped halfpenny falls in a straight line. A short enough bit of any curve is straight, and it is our limited outlook that makes us worship the straight line and its dreadful corollary the right angle. The corners in our rooms are right-angled for no conceivable reason, and the figures of the second book of Euclid and those of our smartest women can be drawn with the aid of the same simple ruler that suffices for the plotting of the work of our most esoteric cubist painters. The Greeks saw the danger of such practical rectitude and subtly curved the columns of the Parthenon. Chinese roofs have gently upturned edges that suggest a smile and give a sense of light insecurity, but that is certainly better than our slated plain superficies. Any curve is more easy to live with than a line whose only merit is that it is the shortest distance between two points.

The New Deptford Consumption Dispensary.

THE first municipal dispensary in London for the treatment of consumption was opened last week at Deptford. The house and land have been presented to the borough as a memorial of his year of office by Mr. E. Mumford Preston, the ex-Mayor, who has also fitted up the institution. It begins its work at once with a staff of one whole-time medical officer, and three qualified female health visitors. Though the gift of the building is due to a single donor, the Deptford Council had already decided to establish such a dispensary, and they will now maintain it out of municipal funds. The compulsory notification of pulmonary tuberculosis placed a valuable power in the hands of authorities, and Deptford is now in a position to take all measures to prevent the spread of the disease. The direct control of the health authority over the dispensary has many advantages. The whole organisation will be carried out under the control of the medical officer, so that the necessary following up of cases and finding out "contacts" are made possible. Preventive measures also can be best carried out under the constant supervision of qualified health visitors. Another advantage is that the continuity of the work is preserved. Voluntary dispensaries cannot give the same guarantee of continuity as is possible where the health authority has charge. There are no beds in the new dispensary. Its function is that of a clearing house, and it is intended to be the local information bureau, where guidance may be sought by anyone. The authorities of Deptford intend to make the new dispensary the local centre of activity in the treatment and prevention of consumption, and they will invite patients from all agencies, social, charitable, or religious.

Food Adulteration.

THE second part of the report of the Local Government Board for the 15 months ending

March last, is now issued. It deals among other things with adulteration of food. It forms a dismal exposure of one part of the seamy side of trade, of that form of commercialism that reckons everything "good business," by which money can be made so long as it does not involve the danger of adequate punishment. Magistrates very rarely inflict more than small fines, even in cases of serious adulteration, and this fact deters local authorities from taking even the grossest cases into Court. The Justices are now being reminded of their duty in this matter by a circular from the Home Office. In the case of milk the fact that the lives of the very young and the very old largely depend upon a pure supply does not deter dealers from deliberately carrying on a deadly system of fraud. Out of 50,849 samples 11.9 per cent. were reported as adulterated, or as failing to reach the minimum limits. Samples informally taken have been found to have had from 30 to 70 per cent. of their fat abstracted. One analyst states that the contrast between the quality of the milk collected in the ordinary formal manner and that taken without formalities is very startling and shows that concealed adulteration is rampant. Among other instances reported are cases of milk treated with annatto in order to give it colour, and with boric acid and formalin to prevent the discovery of decomposition. Margarine is still substituted for butter; dyed cane sugar from Java is sold as Demerara sugar, and salicylic acid is added to wine. Baking powder has been found to contain sulphate of lime, and shredded beef suet to consist partly of oatmeal or cornflour. So-called "cider" consists often solely of coloured, flavoured, and aerated sugar solutions, entirely innocent of any relation to apples. The revelations with regard to the traffic in "screw" or "slink" meat are equally deplorable. Slaughter in public abattoirs under inspection is nowhere enforced, and diseased animals are slaughtered outside towns, often at night; the carcases are cut up and the meat is brought into market in pieces from which portions that might indicate disease have been carefully removed. It is hopeless to look for any immediate abatement of these evils. New legislation is necessary to ensure enforcement of the law, and to make penalties severe enough to be really preventive.

The New Milk Bill.

SINCE our previous paragraph was written there has been published the text of Mr. John Burns's new Bill for the "Regulation of the Sale of Milk." If it becomes law this Bill promises at least to mitigate some of the existing evils and abuses. The Bill gives power to local authorities in populous districts to establish depots for the sale of milk specially prepared for infants under two years of age. The authorities will have power to purchase and prepare the milk and provide such laboratories and plant as are necessary. This applies to districts with a population of 50,000 and upwards, but other districts with a population of not less than 10,000 may also be invested with the same powers on application to the Local Government Board. The Bill also provides for more effective registration of all dairymen and dairies and for inspection of dairies and examination of cows by the local medical officers. In cases where the medical officer is of opinion that infectious disease is caused, or is likely to be caused, by the consumption of the milk from any dairy he is to have the power to make an interim order prohibiting the supply pending the decision of the local authority. Dairymen disputing the need of an order confirmed by the local authority are to have the right to appeal to

a Court of Summary Jurisdiction. A person selling milk which has been declared to be tuberculous and the sale of which has been prohibited by such an order is to be liable to a penalty not exceeding £10.

The Plight of the Hospitals.

THE deficit of £50,000 in the annual income of the King Edward's Hospital Fund for London last year, which was announced at a meeting last week to award the grants to hospitals, convalescent homes, and sanatoria, may be regarded as a sign of the times. It is difficult not to connect the staunching of the flow of public charity with recent legislation, in spite of the guarded optimism of the officials of the Fund. The King, who is the Patron of the Fund, with his characteristic sympathy, has caused a letter to be written to the presiding governor, in which His Majesty expressed his regret to see the diminution in income from subscriptions and donations and that he would look upon any reduction in the total grants as a calamity. This feeling must be shared, directly or indirectly, by all who are interested in the welfare and security of our great voluntary hospitals, not only in London, but also up and down the country. Most, if not all, of the authorities of these institutions view the coming year with much apprehension, on account of the uncertainty as to the effect of the Insurance Act upon their income and administration. Whether State endowment is to be the remedy for the unsatisfactory financial condition of the hospitals remains to be seen. There appears to be no reason, should such a system ultimately be adopted, why the streams of philanthropy should cease altogether, even though they would be somewhat attenuated.

The Psychologist in the Schools.

THE recent appointment of a scientific layman as a half-time psychologist in the education officer's department of the London County Council for a period of three years is another evidence of the progressive character of the work of that body. We gather that part of the duties of this new official will be to assist the headmasters of the Council's schools in the detection of mentally deficient children, as well as to study the habits and characteristics of school children generally from the psychological standpoint. Experimental psychology is closely allied to mental physiology and mental medicine; indeed, it is difficult to imagine either of these subjects being separated from the other, in theory or in practice. Nothing can be said against the scientific attainments of the gentleman appointed, Mr. C. L. Burt, who is lecturer in experimental psychology in the University of Liverpool and the author of several valuable papers upon this science, some of which have been read before the British Association. At the same time it may be urged that some of the problems that present themselves in the case of mentally defective children have such an intimate relationship with general medicine, that only those who have had a complete medical training would be in a position to deal with them adequately. No doubt those medical officers on the staff of the London County Council who have alienist experience will be available for consultation in any case of difficulty that may arise. It will be interesting to watch the development of this new scheme.

PERSONAL.

MISS ELEANOR DAVIES-COLLEY, F.R.C.S.Eng., has been appointed Surgical Registrar to the Royal Free Hospital.

DR. T. LEWIS, M.D., B.S.Lond., M.R.C.P., has been appointed assistant Physician to University College Hospital.

MR. W. GIRLING BALL, F.R.C.S.Eng., has been appointed Surgeon to the City of London Truss Society for the Treatment of Hernia.

MR. W. D. D. SMALL, M.B., Ch.B.Ed., has been awarded the Stark Scholarship in Clinical Medicine in the University of Edinburgh.

MR. DONALD ARMOUR, M.B.Toronto, F.R.C.S.Eng., has been appointed Honorary Consulting Surgeon to the Blackheath and Charlton Hospital.

DR. ROBERT BURNET, Medical Officer of Health for Cornwall, delivered an instructive lecture last week in Truro Town Hall, on "The Public Health of the County."

SIR WILLIAM OSLER, Regius Professor of Medicine in the University of Oxford, was the recipient last week of the Honorary Degree of D.C.L. of the University of Durham.

DR. N. J. TURRELL, M.D., B.Ch.Oxon., has been appointed Honorary Physician-in-Charge of the Electro-therapeutic Department at the Radcliffe Infirmary and County Hospital, Oxford.

PROF. WILLIAM BATESON, M.A., D.Sc., F.R.S., Fullerian Professor in Physiology, will deliver a course of lectures on "The Heredity of Sex and some Cognate Problems" at the Royal Institution, on Tuesdays, at 3 p.m., commencing January 14th, 1913.

MRS. JOHN HALL has given £500 to the University in memory of her husband. The income will provide each year a gold medal to be awarded to the student who does best in the subject of pathology at the examination for the degrees of M.B., Ch.B.

DR. R. DE LA POER BERESFORD, who is shortly retiring from active medical practice, claims to be the senior public Medical Officer of Health in England and Wales. With the exception of one year, when he acted as Mayor of the borough, he has been Medical Officer of Health for Oswestry for 44 years.

DR. H. MACEAN, M.D., M.Sc., an internal student of the Lister Institute of Preventive Medicine, has been awarded the D.Sc. degree in Bio-Chemistry of the University of London for his thesis entitled "A Contribution to the Study of Lipoids—(i.) The Phosphatides of the Kidney. (ii.) On the Purification of the Phosphatides," and other papers.

AT the Royal Bethlem Hospital the following honorary consulting appointments have just been made:—Surgeon, Mr. Arthur H. Evans, of Westminster Hospital; Aurist and Laryngologist, Mr. William M. Mollison, of Guy's Hospital; Ophthalmologist, Mr. John F. Cunningham, of the London Hospital; Gynaecologist, Dr. Thomas G. Stevens, of St. Mary's Hospital; Anæsthetist, Mr. Cecil Hughes, of Westminster Hospital.

A CLINICAL LECTURE

ON

THE SELECTION OF CASES OF PULMONARY TUBERCULOSIS FOR INSTITUTIONAL, DOMICILIARY AND DISPENSARY TREATMENT UNDER THE NATIONAL INSURANCE ACT. (a)

By H. E. SYMES-THOMPSON, M.A., M.D.Cantab., M.R.C.P.Lond.,

Assistant Physician to the Royal Hospital for Diseases of the Chest, London.

THE selection of cases for different forms of treatment presupposes a knowledge of the varieties of treatment which are in view. If, therefore, it be taken for granted that we are familiar with the work of the different establishments for the treatment of tuberculosis it would appear that my task is simply to indicate the different types of case best suited for each form of treatment. But the issue has been complicated by the passage through Parliament of the National Insurance Act. As a result of the part of the Act referring to tuberculosis certain terms, such as hospital and infirmary, gain an altered significance, and the word Sanatorium is used in a broad, and also in a restricted, sense.

The National Insurance Act provides a special organisation for the control and treatment of pulmonary tuberculosis among insured persons, and it is intended eventually to embrace the dependents of insured persons also. The part of the Act dealing with tuberculosis is called "Sanatorium Benefit." This is an unfortunate term, for it comprises measures for the treatment of tuberculosis whether they be institutional (in a sanatorium), a hospital, or a home for advanced cases), or domiciliary (in the patient's home), or at a dispensary. "Sanatorium Benefit," therefore, does not mean sanatorium treatment only, but the treatment of tuberculosis in the manner and at the place which is considered best for each particular patient.

The object of "Sanatorium Benefit" is to develop a system which will be an efficient engine for the treatment of tuberculosis among the industrial classes, and for diminishing the incidence of the disease—the ultimate aim being the eradication of tuberculosis.

The treatment up to now has fallen under three main heads:—

(i) *Domiciliary or Home Treatment.*—Many of the patients undergoing this form of treatment have been doing more or less work. The doctor has done what he could in the home. He has improved the hygiene and supervised the diet and the medicinal treatment.

(ii) *Sanatorium Treatment.*—The number of sanatorium beds has been limited, and, as the doctors have had, as a rule, no special experience of the disease, the wrong type of case has often been sent to the sanatorium, so that comparatively little use has been made of the beds.

(iii) *Infirmary Treatment.*—The value of this form of treatment has also been reduced owing to the fact that the infirmary has the stigma of the workhouse; and patients in many cases have refused to go.

Thus it is that each of these forms of treatment has left much to be desired. The practitioner has had to give domiciliary treatment to many cases which would have been more advantageously treated in the sanatorium or the infirmary. The sanatorium beds have been largely filled with cases which could receive no permanent benefit. And the infirmary has too often opened its doors in

vain to suitable cases. In addition to these disadvantages there has been no central authority governing the whole, and the net has had such large meshes and "lacunæ" that many patients have slipped through and undergone no treatment at all.

The aim of "sanatorium benefit" is to adopt the good points of the old system and to develop its scope. The new arrangements will provide one scheme under a common management, and each part will be correlated and interdependent. All patients suffering from tuberculosis will be under treatment, and each one will be undergoing the particular form of treatment best suited to his case.

Such a large proportion of unsuitable cases have been sent to sanatoria that it is now recognised that an expert must be secured to select suitable cases. The practitioner of the future will have still greater difficulties to face, for it will not be sanatorium cases only which he will have to select, but he will have to classify all the cases and decide between several forms of treatment in each instance. If the practitioner has failed in the selection of sanatorium cases, the situation would become more unsatisfactory still if he were called upon to decide on the treatment for all cases. Owing, then, to the technical nature of the work and as special experience is necessary, it is proposed to hand over the selection of the cases to experts.

Before proceeding to indicate the different parts of the new scheme we must guard against two possible misconceptions. Firstly, the hospitals to which I shall refer will be situated all over the country, so that hospital beds for tuberculous patients will be available in every locality. In this connection we must dismiss from our minds the hospitals as we know them, although they may do the work in their particular areas. The second possible misconception is the position of the "infirmary." In the national scheme the infirmary will be represented by the "special hospital for advanced cases." But as the word "hospital" will be used for another institution, I propose to refer to these establishments as "Homes for advanced cases." The infirmary will continue to exist, but its use will be confined to Poor Law cases.

With these provisos I will indicate the functions to be subserved by the different elements of the national scheme for the treatment of the disease, and we will suppose that we are dealing with some particular district and that the country has been divided up into similar districts with similar facilities.

The Dispensary is the central unit. To it, all cases or suspected cases of pulmonary tuberculosis are sent in the first instance. Here an expert is seen, and so there is a greater probability of an early diagnosis being made than would be the case if the patient had gone to the general practitioner. The dispensary being the distributing centre, it is linked up with a hospital, a sanatorium and a home for advanced cases, and from it patients can be referred to general practitioners for domiciliary treatment. We have in the dispensary not only facilities for early diagnosis, but also, by reason of its executive position as the central pivot for treat-

(a) Delivered at the Royal Hospital for Diseases of the Chest, December 12th, 1912.

ment in all its branches, the advantage that the patient may be at once transferred to the particular form of treatment best suited to the individual case at the moment at which he presents himself. There is also the preventive side of dispensary work, in which the "contacts," that is to say the immediate families of the patients are examined with a view to the discovery of the disease in an early stage.

You will notice that a dispensary is like an out-patient department at a chest hospital in that an expert is seen, and in that it is in connection with a hospital and with sanatorium beds. But it differs from such an out-patient department in that tuberculosis is the only disease treated, and in many other particulars which will occur to you. Moreover, there will be dispensaries all over the country, whereas the chest hospitals are few.

The Sanatorium.—The majority of the cases suitable for sanatorium treatment are the early cases when the fever has subsided, and the chronic afebrile cases. Another suitable class is that in which there is mixed infection—when there are other organisms as well as tubercle bacilli in the sputum. At the sanatorium these secondary organisms usually rapidly disappear so that tubercle bacilli alone can be discovered in the sputum. The non-appreciation of this fact has probably been the cause of much waste of time and energy in the preparation of vaccines for the treatment of secondary organisms.

The Hospital (for in-patients).—The patients to be sent to hospital divide themselves into three main heads:—

(i) Those cases in which we are not sure whether we are dealing with incipient pulmonary tuberculosis or some other disease. If they prove, on investigation, to be tuberculous they are sent to the sanatorium.

(ii) Cases of active disease with an amount of lung involvement ranging from a moderate to an extensive degree, provided that the constitution is not undermined. If they take a favourable course—*i.e.*, if after a week or so in bed the temperature and the pulse-rate fall to normal or nearly so, the patient is transferred to the sanatorium. If, on the other hand, the case proves to be a progressive one and the disease spreads, the patient is transferred to the home for advanced cases.

(iii) Cases with acute complications, such as Pleurisy, Hæmoptysis and Pneumothorax. If the patient does well the case becomes one of simple uncomplicated pulmonary tuberculosis and is transferred to the form of treatment best suited to his particular case.

The Home for Advanced Cases.—Under the new scheme special homes will be set apart for advanced and progressive cases, in which the constitution is undermined. The chief purpose of these homes is to segregate patients, who would otherwise become sources of infection to their families. The importance of these homes will be realised when we remember that many of the patients with advanced disease are expectorating millions of tubercle bacilli every day. The large majority soon die, but a few improve under treatment and are sent to the sanatorium, where the disease may eventually even become quiescent.

Domiciliary Treatment, or treatment in the patient's home. Patients for this treatment comprise:—

(i) Certain cases referred for Domiciliary treatment by the dispensary. These will generally be in an early stage, and present a high degree of resistance to the disease.

(ii) Those who are waiting for beds at the sanatorium, the hospital, or the home for advanced cases.

(iii) Those who have left the sanatorium and

in whom, though the disease is quiescent, we are not sure that arrest has taken place. Under this head would fall patients with arrested disease—*i.e.*, those who have had pulmonary tuberculosis in the past—perhaps twenty years previously—and who have regained their health. Such patients would report themselves to the doctor at regular intervals.

As patients undergoing Domiciliary treatment are continuously under observation, they can be sent at once to the hospital or the sanatorium, as the case may be, should any exacerbation of their disease take place.

(The lecture was illustrated by patients exhibiting different types and stages of the disease.)

NOTE.—A *Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by George Thompson, L.D.S., M.R.C.S., Hon Dental Surgeon at the Royal Hospital for Diseases of the Chest. Subject: "The Teeth in Relation to Pulmonary Tuberculosis."*

ORIGINAL PAPERS.

THE NEUROLOGY OF THE VISUAL SYSTEM.

A Short Series of Original Papers.

By HARRY CAMPBELL, M.D., F.R.C.P.,
Physician to the West End Hospital for Diseases of the Nervous System.

PAPER V.—*Concluded.*

ABNORMALITIES OF THE PUPILS.

The pupils may be abnormal in regard to:—

- (a) Size and shape.
- (b) The Light reflex.
- (c) The accommodation reaction.

(a) *Abnormalities in Respect of Size and Shape.*—The pupils may exhibit marked contraction (miosis), marked dilatation (mydriasis), rhythmic alterations in size (hippus), inequality of size (anisokoria), irregularity (non-circularity) of their free border, and eccentricity.

Miosis.—When not due to adhesions, miosis results from spasm of the irido-constrictor. This is mainly due to an excessive innervation through the third nerve, in only a minor degree to a deficient innervation through the sympathetic. So-called "spinal miosis" has been (probably falsely) attributed to a blockage of sympathetic impulses from disease of the posterior spinal roots of the lower cervical cord. In this way Erb explained the miosis of tabes dorsalis.

Miosis is observed as the result of:—

Gross irritative lesions of the third nerve (*e.g.*, from basal meningitis). Paralysis of the sympathetic (*e.g.*, from tumours of the neck, pachymeningitis cervicalis, syringomyelia, disease in the upper part of the thorax).

The action of miotics—*e.g.*, morphine, eserine, pilocarpine, chloroform, and certain autogenetic toxins—*e.g.*, those of uræmia.

Senility.—One-fourth of the aged have decided miosis. In such the pupils remain powerfully contracted under the influence of moderate light. Small in the morning, they get much larger in the duller light of the evening. The reactions both to light and to accommodation are sluggish in senile miosis. They should be tested in a dark room.

Acute Diseases of the Eyes Causing Photophobia.—In most acute diseases of the eyes the pupils tend to be small, and the miosis is generally associated with photophobia. Here the spasm is obviously protective.

Syphilis (cerebro-spinal lues, tabes dorsalis,

general paralysis).—This is the commonest cause of miosis. In tabes miosis is sometimes very pronounced and gives the eyes, especially when blue, a characteristic appearance, owing to the large amount of iris showing. It may precede the Argyll Robertson phenomenon. Not only in tabes, but in general paralysis of the insane and in cerebro-spinal lues, miosis may occur in association with the Argyll Robertson pupil. When optic atrophy supervenes in such cases the pupils do not undergo the dilatation which ordinarily follows upon optic atrophy. Tabetic miosis is in some way related to the retention of accommodation contraction, for when, in a tabetic patient presenting the Argyll Robertson pupil with miosis, the pupil loses the power of accommodation contraction, the miosis disappears.

Organic Disease of the Brain.—In lesion of the pons the pupil may be small. Also in concussion.

Hysteria.—It is doubtful whether miosis occurs in hysteria, except in connection with semi-voluntary spasm of the internal recti, giving rise to

FIG. 31.—Diagram showing some of the connections of the superior colliculi. The brain stem is seen in horizontal section, while the medulla and cord are seen from behind. Fibres are seen passing from the retina and occipital cortex to the right superior colliculus. The tecto-spinal fibres are seen passing through the medulla to the ventral horns of the cord. A neuron is seen passing from the right superior colliculus to the right third nerve nucleus, and one from the left superior colliculus directly into the third nerve trunk.

accommodation contraction of the sphincters, or as the result of forcible contraction of the orbicularis palpebrarum (orbicularis phenomenon).

The Death Agony.—During the death agony there is generally marked miosis, which at the time of death suddenly gives way to dilatation. This in the course of a few hours is followed by narrowing from rigor mortis, the pupils widening again when the rigor passes off.

Mydriasis.—This results from deficient innervation of the irido-constrictor, or from excessive stimulation of the irido-dilator. It may occur pathologically in consequence of:—

Paralysis of the third nerve: paralytic mydriasis. In this case it is often unilateral. In nine cases

out of ten organic mydriasis is due to syphilis from involvement of the third nerve, in the shape of cerebral lues, tabes dorsalis, or general paralysis of the insane. It is important to remember that syphilitic mydriasis may occur soon after the primary infection. Among mydriatics, atropine, duboisine, daturine, hyoscyamine act by paralyzing the third nerve terminals. In extreme chloroform-narcosis paralytic mydriasis also occurs.

Irritation of the sympathetic: spastic mydriasis. In Graves' Disease the pupils are apt to be large. The mydriasis here, as well as the retraction of the lids, is due to hyperactivity of the sympathetic. An irritative lesion of the sympathetic on one side may cause dilatation of the corresponding pupil. Among mydriatics cocaine acts by stimulating the sympathetic. Spastic mydriasis is met with in a variety of functional nervous diseases—*e.g.*, insanity (in which the mydriasis may alternate with miosis), epilepsy, hysterical seizures, migraine, dyspnoic attacks, uræmic convulsions, painful crises (tic douloureux, lead colic, biliary colic, tabetic pains, the pains of parturition). If in a case of convulsions the pupils are not dilated and the corneal reflex is present, epilepsy can be excluded.

FIG. 32.—Diagram showing the long light reflex arc according to Bach. Fibres are seen descending from the right superior colliculus to the inhibitory light reflex centre near the calamus scriptorius. A further set is seen ascending from this centre. These either pass directly into the trunk of the third nerve, or terminate within the nucleus of the third nerve.

Optic Atrophy.—In marked optic atrophy, light falling upon the retina generally fails to cause reflex narrowing of the pupil, which is thus apt to be dilated. The coarser fibres, subserving the light reflex, may, however, be less involved in the absorption process than the finer visual fibres.

Glaucoma.

Asthenia.—The delicate, the anæmic, the tubercular, and the neurasthenic are apt to have large pupils.

Hippus.—This consists of a rapid rhythmic alteration in the size of the pupil occurring without any external excitation.

Inequality of the Pupils (anisokoria).—Normally the pupils seldom differ more than slightly in size. Congenital inequality sometimes occurs; it may be such that now one pupil, now the other, is the larger (*anisokorie à bascule*). Inequality may occur

in the healthy in consequence of inequality in the refraction of the two eyes.

When not due to disease of the eye itself, such as iritis, or glaucoma, or to refraction error, decided inequality suggests organic disease of the nervous system; especially if the pupils are small. Inequality may result from disease of the nervous apparatus of one eye—e.g., optic atrophy, paralysis of the third nerve, or of the sympathetic. It is common in tabes dorsalis, general paralysis of the insane, and cerebro-spinal lues. At some time or other it is always present in tabes. It may occur in other diseases, such as uræmia and organic disease of the brain—e.g., tumour, hemorrhage, meningitis, deseminated sclerosis.

Transitory inequality may occur in acute meningitis and epilepsy.

Irregularity (i.e., non-circularity) of the Pupillary Margin.—Irregularity has been experimentally produced by stimulating individual ciliary nerves. Putting aside the irregularity resulting from adhesions, this condition is much the most frequently met with in tabes, general paralysis of the insane, and cerebro-spinal lues. It may precede the appearance of the Argyll Robertson pupil.

In the acute phase of glaucoma the pupil is oval; later irregularity may result from irregular atrophy of the iris. Irregularity from a similar cause is not infrequently met with in old people.

A portion of the pupil may be congenitally absent (coloboma).

Eccentricity of the Pupil.—This condition is often congenital and has little diagnostic significance. It has been given as a symptom of disease in the neighbourhood of the corpora quadrigemina.

b. Abnormalities in Respect of the Light Reflex.—Paradoxical light reflex is a supposed widening of the pupil in response to the stimulus of light (and, contrariwise, a narrowing of the pupil when it is shaded). It is probably a secondary dilatation following upon a primary contraction which has passed unobserved. Such a secondary dilatation is a common occurrence; nor must it be forgotten that when light is suddenly flashed into the eye the lids may be forcibly closed. This forcible closure causes a temporary narrowing of the pupil (orbicularis phenomenon), and the pupillary dilatation which follows upon this may erroneously be regarded as a paradoxical light reflex.

The pupils may be immobile, failing to react to any form of stimuli, either as a result of fixation by adhesions, or in consequence of such conditions as cerebral compression, concussion, hæmorrhage, and uræmia.

In the paralytic mydriasis from atropine the light reflex is entirely lost. It persists in a moderate degree in the spasmodic mydriasis caused by cocaine; similarly, in the spasmodic miosis produced by eserine and pilocarpine some light reflex is usually retained.

In disease of the retina or of the optic nerve (e.g., optic neuritis, or optic atrophy) causing complete interruption of light stimuli, the light reflex is necessarily lost. In such cases (e.g., in complete blindness from double optic atrophy) the contraction on accommodation and convergence is preserved. Usually the light reflex is retained so long as any sight remains, and it may even be present when there is complete blindness.

In unilateral optic atrophy, even though the direct light reflex is lost in the affected eye, the pupil of the latter may be made to contract consensually through the sound eye. On the other hand, the pupil of the sound eye cannot be made to contract consensually through the affected eye.

In hemianopia resulting from disease of the optic chiasma or optic tract, light falling upon the blind

portions of the retina fails to evoke the light reflex (Wernicke's sign). On the other hand, hemiopic loss of light reflex is said sometimes to occur without hemianopia, when a limited lesion interrupts the light reflex fibres just after their separation from the visual fibres, close to the superior colliculus. (Fig. 30.)

In recovery from optic neuritis the light reflex may recover perfectly, while sight recovers partially only. In other cases sight is regained before the light reflex. Optic neuritis may affect the light reflex fibres more than the visual, and *vice versa*.

When, without any disease of the retina, optic chiasma, or optic tract, the pupil fails to contract in response to light but contracts upon accommodation, the condition is known as the Argyll Robertson pupil. This phenomenon is practically pathognomonic of tabes, general paralysis of the insane, or cerebro-spinal lues. It is most common in the first of these, least common in the last.

Short of complete loss of the light reflex, the pupils may respond sluggishly to light. They may similarly respond sluggishly to accommodation and convergence. This sluggish reaction is suggestive of a syphilitic or meta-syphilitic disease of the nervous system.

The "myoclonic pupillary reaction" may be referred to here. This consists of a continuation of miosis for some time (one to two minutes) after the removal of the exciting cause (e.g., light, accommodation). It occurs most frequently in syphilitic and meta-syphilitic disease.

In testing for the Argyll Robertson pupil the patient should look into the distance, so as to obviate the effect of convergence and accommodation. We must make sure that there is no disease of the retina or optic nerve; and bear in mind that the forcible closure of the lids, which may result from sudden entrance of light into the eye, may cause the pupil to contract.

The sensibility of the retina to light reflex stimuli is greatest in the region of the macula, diminishing thence outwards. A pupil which fails to contract to bright daylight after even prolonged shading, can sometimes be made to contract in the dark room by concentrating light on the macula by means of a lens.

The pathology of the Argyll Robertson pupil has not wholly been cleared up. The condition was once attributed to selective degeneration of the anterior portion of the third nerve nuclei. In the light of Marina's observations this view can no longer be held. In all the cases of Argyll Robertson pupil which this observer has examined *post mortem*, he has found degeneration of the cells of the ciliary ganglion and of the ciliary nerves, while the oculomotor nuclei have been intact.

Abnormality in respect of accommodation.—Spasm of accommodation is common, and may be so great as to cause a high degree of myopia. This condition is frequently met with in nervous children, and is occasionally seen in young adults. Though it may occur in hysteria it is doubtful whether it is a hysterical phenomenon. In these cases of ciliary spasm there is no corresponding spasm of the irido-constrictor. This shows that the nervous mechanism subserving each of these correlated phenomena may functionate independently. Eserine and pilocarpine, which produce miosis, cause also spasm of accommodation. Atropine and duboisine cause paralysis of accommodation; also paralysis of the third nerve. In states of debility accommodation is often weakened.

Loss of accommodation narrowing without loss of light reflex is rare. It occurs most frequently in diphtheria in conjunction with paralysis of the ciliary muscle. Nothing is known concerning the exact seat of the lesion in loss of this reaction.

Syphilis more frequently causes loss of accommodation than diphtheria, but in the former disease the remaining intrinsic muscles are involved at the same time.

In Botulism accommodation may be paralysed alone or in conjunction with other ocular palsies.

The power of accommodation diminishes with advancing years. It is therefore difficult to test for paralysis of accommodation in the aged.

A NOTE ON INTESTINAL STASIS. (a)

By R. MURRAY LESLIE, M.A., B.Sc., M.D.,

Physician, Prince of Wales's General Hospital.

The subject of intestinal stasis is extremely important from the standpoint of the physician. The brilliant researches of Mr. Arbuthnot Lane have thrown new light on the whole question of functional disturbance of the gastro-intestinal tract, of which dyspepsia and constipation are merely symptomatic manifestations.

Intestinal stasis consists essentially in the arrest of normal peristalsis, or such interference as to render the peristaltic movements inefficient in preventing undue accumulation of intestinal contents. The stasis may be produced either by neuromuscular atony or by mechanical obstruction. Neuro-muscular atony may be congenital, or it may be associated with anæmia, neurasthenia, and other debilitating conditions, or, indeed, may be the result of sedentary habits, especially when associated with matutinal neglect. The nervous factor may manifest itself by a defective reaction to natural stimuli, which may be either natural to the individual or due to a temporary lowered vitality of the nerve centres, as in neurasthenia. Dietetic errors, including the taking of semi-solid, pulpy food containing an insufficiency of solid stimulating residue, also play an important part.

The condition known as enterospasm, which in women may take the form of spasmodic constriction of a portion of the colon, is a not uncommon accompaniment of hysteria and neurasthenia, particularly when these are associated with painful pelvic affections, and if, as sometimes happens, we have atony of one part of the large bowel, with enterospasm of the portion immediately beyond, there is present a combination which specially favours the occurrence of intestinal stasis.

As regards mechanical obstruction, it is only within the last few years that we have begun to realise the important rôle played by mechanical obstruction and its far-reaching effects. In common with many others, I was at first extremely sceptical as to the presence and significance of the various adhesions and kinks described by Mr. Lane; but six years ago I became a convert as the result of my observation of a particular case of chronic intestinal stasis of 13 years' standing. All medical and hygienic remedies having proved unavailing, I consulted Mr. Lane, as the patient appeared to be sinking from emaciation and asthenia. At the short-circuiting operation several thick, adhesive bands were clearly demonstrated, which were certainly abnormal. The patient, who had been a miserable, chronic invalid for many years, now enjoys perfect health, and has been able to play seven sets of tennis without undue fatigue. She gained two stones in weight after the operation. My later experience of a considerable number of similar operation demonstrations, in most cases preceded by radiographic examinations, has only tended to strengthen my belief in the importance of these adhesive structures and kinks, and I feel I can with confidence predict that a similar view will

sooner or later be universally accepted by the medical profession.

In my own experience, the two facts that stand out prominently are the enormous preponderance of cases occurring in the female sex, and the frequent association with enteroptosis. Out of some fourteen successive cases of well-marked intestinal stasis that have recently been under my care, all have been women, and with the exception of three, all exhibited X-ray evidence of enteroptosis to a greater or less degree. The average age of these patients was 35, the ages varying from 29 to 44. I had one case (not in this series) of an old lady of 72 years of age. In the above series of cases, the average period between the onset of symptoms and the date of coming under observation has been twelve years. There has generally been a history of constipation, commencing in early adult life (18 to 24) the more remote symptoms of auto-intoxication, including emaciation and asthenia, becoming pronounced between the ages of 30 and 45. Another curious fact in the series is that with three exceptions all the patients were unmarried, which confirms Mr. Lane's views in regard to the beneficial effects of matrimony as a counteracting influence.

The explanation of this sex preponderance I believe to be due to the fact that enteroptosis is probably by far the most important primary causal factor in the production of intestinal stasis. Meinert found visceroptosis in 80 per cent. of his gynæcological patients, visceroptosis being fully ten times more common in the female than in the male. This greater frequency may be attributed to the following causes:—(1) the less marked obliquity of the female pelvis (so that the pelvic cavity, in addition to having greater width and capacity, is more of a continuation of the elongated female abdominal cavity, while the more expanded pubic arch gives less direct support to the overlying viscera); (2) the more lax condition of the abdominal walls in women (which offer less resistance to downward pressure and which may be accentuated by over distension due to repeated pregnancies and other causes); (3) the wearing by women of wrongly constructed corsets (which Einhorn believed to be an important causal factor, particularly when the corset exerts pressure on the base of the thorax and upper part of the abdomen, thus forcing the organs downwards); (4) the almost universal adoption in civilised countries of the sitting posture in the act of defæcation, in contrast to the natural crouching one, the present high lavatory seats being specially harmful in the case of women and children; and (5) the greater tendency to neurasthenic debility and constitutional weakness of the mesenteric and other peritoneal attachments.

As regards the symptomatology of intestinal stasis, my series of cases tends to confirm the truth of Mr. Lane's observations in regard to auto-intoxication, though I am inclined to join issue with him in regarding the frequently associated neurasthenia as necessarily in all cases a sequela of intestinal stasis. I believe that, in not a few instances, neurasthenic debility is in reality a precursor of the stasis and a not unimportant causal factor—possibly hereditary. It would be impossible to enumerate all the symptoms manifested by these patients; the most important have been general languor and inertia, irritability, mental depression, cold, clammy and livid extremities, dark staining of the skin, muscular debility, incapacity for prolonged physical or mental exertion, and progressive emaciation. A nodular condition of the breasts was often present in the advanced cases. Spasmodic dragging or abdominal pain and tenderness were present in varying degrees in most advanced cases,

(a) Substance of remarks at a discussion held on December 9th, 1912, at the Medical Society of London.

and in practically all of these we found evidence of definite obstruction, due to ileal kinks, duodeno-jejunal kinks, angulation of the flexures, or fixation and impaction of the cæcum or sigmoid in the pelvis. It may be taken as an axiom that whenever there is pain there is obstruction somewhere. In several cases the radiographic evidence was confirmed at the subsequent operation. It is noteworthy that in some cases of enteroptosis and intestinal stasis there were remarkably few symptoms, while other patients, in some of whom the condition seemed less advanced, were in a miserable condition of ill-health. In the former a condition of tolerance seems to have been established.

I may take this opportunity of emphasising the great importance of radiography in diagnosing the presence of visceroptosis, the presence of kinks or impactions, the site of the obstruction, and the full extent of the stasis. In the visceroptosis cases there are generally the two cardinal features: (1) Discomfort and inertia get worse as the day goes on; (2) are relieved by lying down.

As regards remote sequelæ, I have had instances of cystic change in the left ovary, which had become involved in the sigmoid adhesions, appendicular irritation, mucous colitis, gall stones, and gastric dilatation, but have had no experience of actual gastric or duodenal ulceration of stomach or duodenum, carcinoma, or tuberculosis following intestinal stasis.

With reference to treatment, I can speak strongly of the value of liquid petroleum in association with abdominal massage, exercises and electricity, while in the visceroptosis cases much benefit results from the use of properly constructed corsets and abdominal supports.

As regards operative measures, resection of the bowel, or even short-circuiting, seems heroic treatment, even for obstinate constipation. I have, however, had experience now of several cases in which simple measures had been tried, without avail, to relieve the constipation and abdominal pain and to check the progressive ill-health, and in which I felt it my duty to advise operation. The dividing of the ileum and the short-circuiting of its termination into the pelvic colon or upper part of the rectum has proved more than satisfactory, and the patients are all now enjoying good health. In Mr. Lane's hands the operation appears to be attended by but little risk.

If the results are so good, it is surely better in advanced cases, where simple remedies have failed, to have recourse to this radical cure for intestinal stasis, rather than leave the patient in a miserable state of suffering and chronic invalidism, rendering life almost insupportable, and so lowering the resistive power of the tissues, owing to the effects of auto-intoxication, as to frequently endanger the life of the individual from intercurrent complications or otherwise.

SOME CASES ILLUSTRATING THE DIFFICULTY AND IMPORTANCE OF EARLY DIAGNOSIS IN ACUTE INTESTINAL OBSTRUCTION.

By ERNEST W. HEY GROVES, M.S., F.R.C.S.,

Assistant Surgeon to the Bristol General Hospital.

IN forming a complete clinical picture of a typical case of intestinal obstruction, it is necessary to assemble all the signs and symptoms of this condition as forming parts of a whole; but it is of the utmost importance to remember that in the majority of cases diagnosis must be made and action must be taken, long before the picture is complete. We must be prepared to act upon a reasonable probability, and

not wait for convincing demonstration in many surgical conditions, notably in acute abdominal disease and in the case of malignant growths. The following cases are all those of acute obstruction of the bowels (*a*) which came under the writer's care within fifteen months, exclusive of those of strangulated hernias; and they illustrate in a striking manner two important points, viz. first, on what slender ground a diagnosis must often be founded, or rather how the exact diagnosis must often be deferred until after opening the abdomen, and second, what extreme changes occur in the intestine in a very short time.

CASE 1.—Enteric intussusception (Fig. 1). S.H., æt. 24, working man. Admitted to the Cossham Hospital June, 1910, for abdominal pain.

History.—No previous illness. Twenty hours before operation he felt a sudden pain in the abdomen just as he was rising from bed; this was followed by slight vomiting. The pain continued

FIG. 1.

without much change, but the vomiting did not persist.

Condition.—Uniform distension of the abdomen, with some diffuse tenderness. Pulse 110, temperature normal. Bowels not open since the pain began.

Operation was decided upon at once because of the distension associated with persistent pain and constipation. Median incision, quantity of blood-stained exudate. A large coil of black gut, each limb being about one foot long and two inches in diameter, was easily brought to the surface. It consisted of an intussusception of the upper part of the jejunum, and the highest part of the superior mesenteric vessels was dragged into its neck. It was necessary to reduce the invagination in order to clear the neck from these important vessels. This was a matter of some difficulty, and in doing it the ensheathing layer was torn in several places. A piece of gut measuring four feet nine inches in length was resected, this being about two inches more than the gangrenous portion. The cut ends of the gut were closed by purse-string sutures, and a lateral anastomosis formed.

The patient made a rapid and uneventful recovery. A peculiar fact was discovered in subsequent examination of the resected gut, viz. that a polypus about the size of a small walnut was growing from the mucous membrane in the neck of the entering layer. This was proved to be a simple adenoma. The existence of a polypus at the apex of an intussusception is, of course, well known to be a common cause of the condition; but it is almost unique to find such a growth at the neck, and its relation to the invagination is difficult to surmise.

(a) *Bristol Medico-Chirurgical Journal*, March, 1912.

CASE 2.—Strangulation under a band (Fig. 2). John S., *æt.* 55, labourer. Admitted to the General Hospital June, 1910, for abdominal pain.

History.—No previous illness. Sudden pain in the abdomen twenty-eight hours before the operation. He was in the hospital for twelve hours before the gravity of his condition was realised. During this

FIG. 2.

time he had a little vomiting, but the bowels were opened after an enema. The temperature was normal, but the pulse rose to 120, and the abdomen became slightly distended.

Operation was decided upon because of the steadily rising pulse rate and the abdominal pain and distension. Median incision. A quantity of foul-smelling, blood-stained fluid escaped, and a large distended coil of black gut was found strangulated under a long thin band, stretching from the right iliac fossa up to the right side of the mesentery. This band was as tight and as thin as a fiddle-string. The vessels in the imprisoned piece of intestine, which was a high part of the jejunum, were thrombosed, and the foul smell of the exudate proved that rapid transudation was taking place through its devitalised wall. The gangrenous gut, measuring a little over two feet in length, was resected by the cautery. A lateral anastomosis was done after closing the open ends of the bowel. The wound was drained. The patient made a rapid recovery, and has since been quite well.

CASE 3.—Tuberculous peritonitis (Fig. 3) Mervyn T., *æt.* 13, admitted to the General Hospital, August, 1911, for severe abdominal pain.

History.—He had been healthy until one year previously, since which time he had had several severe attacks of abdominal pain. On two occasions he had been admitted to the Hospital on this account, once under a physician and once under a surgeon, but both times he had been discharged because nothing definite could be detected which required active treatment. On the present occasion the pain has been unusually severe, but he has taken his food well and the bowels have acted regularly.

Condition (August 23rd, 1911).—A rather thin boy, in whom no objective evidence of disease could be discovered. The abdomen moves well, it is not tender, but rather full. The pain which occurs in paroxysms is very severe, and at night he keeps the other patients awake by his screams.

Operation was in this case determined on simply on account of the severe pain. Median para-umbilical incision. Some clear free fluid. Extensive tuberculous peritonitis, with many caseous glands in the mesentery. A tight band about half an

inch wide, connected at one end to the right side of the mesentery and at the other to the lumbar parietes on the left side constricted the jejunum about twelve inches from the duodenum. This was divided. The gut beneath the line of constriction was so thin and ecchymosed that it had to be sewn over. The boy made a good recovery.

In this case the absence of vomiting and constipation is especially noteworthy.

CASE 4.—Strangulation by a Meckel's diverticulum. Lily W., *æt.* 11. Admitted to the Cossham Hospital April, 1911, because of abdominal pain and vomiting.

History.—Had had chorea for some months. On April 26th she had sudden abdominal pain, but was not ill enough for the doctor to be sent for. Bowels acted with a normal motion. April 27th she was no better, the pain being more constant, and localised on the right side. Dr. Skelton saw her, and thought she had appendicitis. Admitted April 28th.

Condition.—Appeared to be very ill. Pulse 120, respiration 40, temperature 99deg. Abdomen distended and tender, more so over the right iliac fossa, which region was also somewhat dull to percussion. Bowels acted slightly after a turpentine enema. Diagnosis of acute appendicitis.

Operation.—Appendix incision. Free blood-stained fluid. Some coils of distended black gut appeared, and it was necessary to make a median sub-umbilical incision. The lower end of the ileum was tightly strangulated by a cord, the thickness of a sash-cord, wound round the base of the affected loop. This being quite gangrenous was resected, forty inches in all being removed. The gut was reunited by an end-

FIG. 3.

to-end union. The appendix was brought out through the wound, cut short, and used for continuous saline infusion. Her condition improved for about six hours after the operation. She then vomited a large quantity of blood-stained fluid, and died suddenly. There was no autopsy.

If the likelihood of acute intestinal obstruction had been suspected in this case, an early operation would have been performed, and the life might have been saved.

CASE 5.—Strangulation by appendix and Meckel's diverticulum (Fig. 4). Raymond B., *æt.* 6. Admitted to General Hospital September, 1911.

History.—No previous illness. On September 9th he woke up at 4 a.m. with sudden abdominal pain, which was followed by vomiting. This continued all day. The bowels were not open. On September 10th the vomiting had ceased, but the pain continued.

Condition.—Looked ill. Temperature 100deg., pulse 120deg. Abdomen a little distended, some signs of free fluid, an indistinct mass felt in the right iliac fossa. Diagnosis was made of acute appendicitis, and immediate operation performed.

Operation (September 10th, 1911).—Appendix incision. Gangrenous gut presented. Mid-line incision. A short loop of ileum was tightly surrounded

FIG. 4.

The upper diagram in this figure shows the manner in which the appendix and the diverticulum first become adherent to one another so as to form a band which subsequently ensnares a loop of intestine.

at its base by a cord consisting of an appendix which was sloughing, and a Meckel's diverticulum adherent to one another. The gangrenous gut (about six inches), together with the appendix and the diverticulum, was resected, and an end-to-end junction made. A venous infusion of saline solution with pituitary extract was made at the end of the operation. Later in the evening a continuous subcutaneous saline infusion was carried out. He survived only about eighteen hours, dying in the afternoon of September 11th.

CASE 6 (Fig. 5).—Strangulation by the pedicle of a fibroid. Martha C., *et. 71*. Admitted to the General Hospital on September 10th, 1911, for abdominal pain.

History.—She had been told by Dr. Aust Lawrence twenty years ago that she had a "tumour of the womb," otherwise she has always had good health. Early in the morning of September 10th she was taken with severe abdominal pain, with a little sickness. The bowels had since been slightly opened.

Condition (eighteen hours after onset).—She had a drawn and anxious expression. Pulse 120deg. Temperature 97.4deg. The abdomen was soft and not distended. There was slight general tenderness. An enlarged nodular uterus filled up the pelvis. Immediate operation.

Operation.—Sub-umbilical incision. A large quantity of almost pure blood escaped from the incision. A loop of ileum was strangulated in the pelvis by the thin pedicle of a sub-peritoneal fibroid, turned back into Douglas's pouch. This fibroid pedicle was so slender that it broke on manipulation, but it had served to cause gangrene in the coil of incarcerated gut. This, amounting to about three feet, was resected, and a side-to-side anastomosis performed. The patient died in spite of a venous saline infusion performed on the table.

My special object in presenting this short series of consecutive cases is to illustrate and emphasise the difficulty and importance of making an early diagnosis in conditions of intestinal obstruction.

It will have been observed that the history in all of these was comparatively short (between eighteen hours and three days). Now it may be true that a case of intestinal obstruction will live for a whole week in the absence of any operative relief, but in

the majority of cases the fate of the affected gut is determined, and immediate operation demanded within twenty-four to forty-eight hours.

It is utterly unjustifiable to wait in any case of suspected intestinal obstruction beyond this time. A longer period may be necessary for the development of the full clinical picture, with the sunken features, faecal vomiting and abdominal distension, but if one is to wait for this before acting, one might as well wait a little longer for the *post-mortem* examination.

FIG. 5.

The vomiting in the early stages is only slight and transient, as is seen in all the above cases. It is caused by the sudden peritoneal stimulation in the same way as the early vomiting of appendicitis. The faeculent vomiting, which perhaps is the only unmistakable sign of obstruction, is a comparatively late phenomenon, caused by the reflux of fluid from the contracting bowel. It is always desirable to operate before the advent of this evidence of the advanced progress of the malady.

It seems to me that persistent abdominal pain of a severe type, unrelieved by rest and starvation, must remain the most notable sign, and often the only one, upon which a diagnosis is to be founded. When I say diagnosis, it should be noted that in most cases it is only possible to go so far as to say that some grave catastrophe has occurred which demands further investigation. The case may turn out to be one of appendicitis, intestinal obstruction or pancreatitis, but it is better to "look and find out" than to "wait and see."

With certain precautions, the general rule that persistent abdominal pain, unrelieved by rest and starvation, requires the abdomen to be opened, will often be the means of saving life, though very rarely it may lead to an unnecessary operation. By persistent abdominal pain, in relation to the acute conditions we are considering, is meant pain with an abrupt onset in a patient who has been in good health, which persists for more than twenty-four hours, although the patient has been kept in bed on the lightest possible diet.

Such conditions as lead colic, tabes dorsalis, tuberculous spine and aneurysm must be borne in mind, and each can usually be excluded by the absence of characteristic signs.

The only condition likely to be mistaken for intestinal obstruction, in which operation will lead to disaster, is the acid intoxication of children. In this there is persistent vomiting, but there is a marked absence of pain, a tendency to drowsiness, and a sweet smell in the breath which should serve as warnings, which will be confirmed if the acetone bodies are found in the urine.

OPERATING THEATRES.

HAMPSTEAD AND NORTH-WEST LONDON HOSPITAL.

LONG OBLIQUE FRACTURE OF THE FEMUR.—MR. JACKSON CLARKE operated on a tall, broadly constructed and very stout woman, who said her weight was 17 stone. She had fallen on getting out of a motor omnibus on her right knee. She had been unable to rise, and was brought to the hospital on an ambulance. On admission the right thigh was seen to be greatly swollen, especially in its lower three-fourths; the knee joint appeared to be normal and on palpation marked tenderness was found extending from a point on the outer surface of the femur at the meeting of the uppermost and second fourths of the bone to another point immediately above the inner condyle. A very oblique fracture was diagnosed, and it was decided that immediate operation was advisable.

Open ether was administered by Dr. G. A. Barton, and an incision made on the antero-external aspect of the limb from a little below the great trochanter to slightly above the knee. At each extremity the incision was prolonged inwards for three or four inches; the integuments being raised and drawn inwards, the rectus was separated from the vastus externus and also drawn inwards, exposing the front of the crureus muscle, which was incised down to the fracture, giving vent to several ounces of liquid blood. The length of the cleavage was now seen to be about twelve inches, the lower end of the upper fragment being just below the adductor tubercle, and the upper end of the lower fragment ended in a sharp point on the outer aspect being displaced about an inch upwards. There was a lateral separation of about three-quarters of an inch between the two fragments, the space between them being filled with recent blood-clot, which was removed without interfering with the bone marrow, to which it was adherent. The shape of the fragments was such that no form of plating was applicable to them, and it was decided that wiring would answer every indication if properly applied. The sharp point on the lower fragment was cut off to prevent its tearing either the tissues or the gloves of the operator, then two holes were drilled near the upper extremity of the lower fragment about three-quarters of an inch from each other; next two drill holes were made at points in the upper fragment corresponding anatomically to those made in the lower fragment, near the lower end of the lower fragment, and at corresponding points in the upper fragment drill holes were made. Now a piece of stout, well-annealed silver wire was passed first through the uppermost drill holes from the outer to the inner, then brought back from the second inner to the second outer; another wire was passed in the same way through the corresponding pairs of holes at the lower ends of the fragments. Downward traction was now made on the limb and the two wires were twisted progressively as the fragments came into position; this they did perfectly. As an extra precaution, a third wire was made to encircle the now reunited bone and twisted taut. Redundant wire was then cut away, and the twisted portions beaten flat against the bone. The muscles and fasciæ were reunited with a few stout catgut sutures and the skin incision was closed with sutures of silkworm gut. Dressings were then applied; a single Thomas's Hip splint was put on and three malleable metal splints applied to the anterior internal and external aspects of the limb respectively, and held in position by a few turns of bandage.

The post-operative course was uneventful, the splints and dressings were removed at the end of the third week and the stitches taken out, the wound having healed by first intention, the limb having its normal shape and length.

TRANSVERSE FRACTURE OF BOTH BONES OF THE LEG.—The same surgeon operated on a muscular young man who had been injured when playing football. On admission the fracture was about the middle of the leg and the upper end of the lower fragment projected forwards under the skin. The limb was put up on a

wooden back splint with side splints, and a skiagram taken through the splints showed that much of the displacement persisted. An open operation was decided upon, and after the usual preparation an incision was made first over the fracture in the fibula. The muscles and periosteum were much torn about the site of this fracture. A four-hole Lane's plate was applied by means of the usual instruments. The fracture in the tibia was next exposed, a curved incision being made; its ends were over the crest of the tibia, the rest of it lying over the anterior muscles. A flap was then turned upwards and inwards, the fractured surfaces being exposed; the periosteum was found to be torn, and there was a collection of about two ounces of clotted blood under the skin. The fracture was transverse, but there were numerous fissures extending a short way from the broken surfaces in both fragments. The plate and screw Mr. Clarke here used were those recently designed and introduced by the American surgeon Sherrard; the plates are made of vanadium steel, which allows of their being bent to any desired degree. The screws have a groove cut on each side near their ends, so that they act to some extent as drills as well as screws. Sherrard's combined screw-driver and screw-holder is, Mr. Clarke pointed out, a most ingenious and effective instrument, and the time required for fixing the bone-plates is greatly diminished by using it and the special screws. The plate was applied to the outer surface of the tibia, so it was covered by a thick layer of muscle when the wounds were closed in the usual way.

Mr. Clarke said the first case was an example of a fracture requiring operative treatment, and the fragments being of such a form that they could not be fixed by plates, but were perfectly fixed by the older method of wiring. In the second case, the fractures being purely transverse, were perfectly suited to fixation by plating.

TRANSACTIONS OF SOCIETIES.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD AT THE STAFFORD ROOMS, THURSDAY, DECEMBER 12TH, 1912.

The President, Dr. H. J. MACENOV, in the Chair.

MR. CHARLES W. M. HOPE read a paper on
SUPPURATION IN THE NASAL SINUSES.

After describing their anatomy and development, and the ætiology of sinus infection, he discussed the various nose, eye, ear, cranial and general symptoms. Many cases, he said, first came under notice on account of troubles otherwise than nasal, and instanced the case of a patient who came to him on account of deafness in the right ear, due to middle ear catarrh, the cause of which was a foul maxillary empyema on the same side.

After describing the various methods of examination carried out to reach a definite diagnosis, he briefly described the treatment, operative and palliative, necessary for each individual sinus. The paper was well illustrated by means of bony and recent specimens, and some X-ray photographs.

The paper was discussed by Dr. SCANES SPICER and Dr. MATTHEWS, and Mr. HOPE replied.

Dr. SPILSBURY then read a paper on

INJURY AS A PREDISPOSING CAUSE OF NEW GROWTHS.

He pointed out that tumours of the more superficial parts of the body were the ones in which a history of injury was most frequently obtained. Taking the bony skeleton he showed the tumours occurred with greater frequency in those bones which were more frequently injured and in those parts of the bones which were more superficial.

In the case of brain tumours, the tubercular as well as the neoplastic, not only was there a frequent association with injury, but in some cases a remarkable relationship of the tumour to the injured area either immediately beneath it or in the centre-coup position. Again, in melanotic growths of the skin, injury or

chronic irritation by clothes or otherwise appeared frequently to be a cause of tumour development. In testicular or mammary tumours injury was probably a less frequent predisposing cause.

The paper was discussed by Dr. SCANES SPICER, Mr. HOPE, and the PRESIDENT, and Dr. SPILSBURY replied.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD AT THE WEST LONDON HOSPITAL,
DECEMBER 6TH, 1912.

BEFORE proceeding to the business of the evening, Mr. BISHOP HARMAN presented three patients for examination.

Cases 1 and 2 both showed senile central choroiditis with deposits of cholesterine crystals in the degenerate tissue. The maculæ were practically destroyed, gave a "worm-eaten" appearance, and glistened like jewelled patches. Angio-sclerosis and some lenticular changes were apparent. Vision was bad. (3) A boy with unusually well-marked opaque nerve fibres in the left eye. A plume-shaped radiate white patch, springing from the lower edge of the disc, passed below the macula, and vessels were seen embedded in its fibres. The condition had no pathological significance, and was distinguished from a pathological exudate by the complete absence of any signs of inflammation, such as haze or puffiness of the retina.

The President, Dr. G. P. SHUTER, then took the chair, and said he had much pleasure in announcing that Sir Berkeley Moynihan had consented to deliver the next Cavendish Lecture; also that the annual dinner of the Society was arranged for February 6th. He then invited Mr. W. Sampson Handley to read his paper on

PELVIC APPENDICITIS AND ITS TREATMENT.

Mr. SAMPSON HANDLEY commenced by stating that the paper was based upon his experience of the disease, and dealt with those peculiarities which characterise appendicitis when the appendix occupied a pelvic position; the pelvic signs and symptoms which might arise in connection with a normally placed appendix were not considered. Early operation was specially important in pelvic appendicitis because in the earliest clinical stage of the disease the appendix might be gangrenous or distended to the point of rupture, and because in the pelvis the formation of a small localised abscess round the appendix was the exception. More usually an unlocalised peritonitis resulted, which was very apt to produce inflammatory paralysis of the pelvic intestines. The pelvic ileum was intensely congested, œdematous, sharply kinked, and immobile, while the ileum above the pelvis was distended but not inflamed. The obstruction was moreover a duplex one, for he was able to show from his cases that the pelvic sigmoid also was the seat of obstruction, a fact of great importance in treatment. Clinically the disease might be divided into three stages—(1) the stage of hypogastric colic, or ambulatory stage, (2) that of intestinal obstruction, (3) that of peritonitis. Frequently cases were first seen by a medical man in the second stage, for the subjective signs were less marked if the appendix lay in the pelvis. The clinical signs were next dealt with in detail. Pain on micturition and the absence of rigidity and swelling in the right iliac fossa were especially referred to. A retro-cæcal appendicitis, with trickling of pus into the pelvis, might closely simulate a pelvic appendicitis. Moreover, a pelvic abscess was a common result of inflammation of a normally placed appendix. In such cases intestinal obstruction rarely resulted, and the prognosis was much better than in true pelvic appendicitis. Other points in diagnosis were dealt with. In regard to the treatment of seven cases operated upon during the first forty-eight hours after onset, all recovered. Ileo-cæcostomy was necessary in only two of these cases. Of eight late cases, some of whom were first seen in a hopeless condition, five died. It was essential to decide definitely whether inflammatory obstruction was or was not present. In the presence of obstruction an ileo-cæcostomy was

necessary. Remembering that the pelvic sigmoid was also paralysed, it was necessary to provide a temporary safety-valve for the large intestine by tying a catheter into the cæcum. Ileo-cæcostomy combined with cæcostomy was the method of choice for obstruction of pelvic inflammatory origin.

The PRESIDENT, after thanking Mr. Sampson Handley for his interesting and instructive paper, said he would like to hear the views of members on the relationship between pelvic appendicitis and disturbed menstruation, a subject only briefly referred to in the paper. He had seen many remarkable cases in which one might have expected to find some relationship, but in vain. On the other hand, he had observed cases in which there was great derangement, often with severe pain, although the inflamed appendix was far removed from the organs concerned. Another point he wished to hear discussed was the best method of drainage in pelvic appendicitis associated with abscess. The late Mr. Bidwell opened and drained such abscesses successfully, in a very large number of cases, through the rectum without making any abdominal incision. The great advantages of this method were: (1) no wound in the belly wall, (2) pus evacuated by its natural route, (3) avoidance of shock from a prolonged operation, (4) no disturbance of inflamed or adherent intestine.

Mr. ASLETT BALDWIN laid stress on the insidious formation of appendix abscess in the pelvis. He considered drainage through the rectum or vagina the best method of dealing with a soft lump felt in either situation, but if the abscess burrowed into the abdomen incision above would be required as well. After about two months the appendix could be removed through an abdominal incision, and in this way hernia through the belly wall was best avoided. In his experience short-circuiting or opening the intestine had not been required in anything like so large a proportion of cases as in the series described by Mr. Handley, and he thought this had been avoided by the sitting position, eserine salicylate and pituitary extract hypodermically, and calomel by the mouth. Not long ago he had a severe case in which the small intestine relieved itself through the upper part of the abdominal incision, and he had to operate twice to close the hole in the bowel.

Mr. RICKARD LLOYD related a case in which the sudden onset of the symptoms at first suggested a perforation of the stomach, but next day symptoms of an acute affection of the right ovary or appendix developed. At operation the appendix was found adherent to the right ovary, and both presented evidences of long standing inflammation and were suppurating. The appendix, ovary, and a calcareous lumbar gland were removed, drainage was secured, and the patient recovered. In another case a child, *æt.* 12, was affected with colic, and on rectal examination, with a view to excluding impaction of feces as a cause of the colic, a prolapsed appendix was felt. Within two days an exploratory laparotomy revealed a gangrenous appendix with a little turbid fluid in Douglas's pouch. The day following the operation the girl seemed convalescent, but on the third day showed signs of jaundice, became maniacal, and died on the fourth day.

Dr. J. A. MANSELL MOULLIN agreed that the diagnosis between appendicitis and diseases of the uterine appendages was often a matter of difficulty, especially in chronic cases; but he did not think that the relationships referred to by the President were of much value from a diagnostic point of view, as menstrual irregularities were due to so many causes.

Mr. F. G. LLOYD drew attention to statistics proving that 70 per cent. of cases of appendicitis recovered without surgical interference. Nature was wonderfully protective and conservative in many instances if the patient was kept at rest, and he advocated operation in the quiescent period when possible. On the other hand it was important not to delay operation when the physical signs and condition of the patient appeared to justify intervention. He also referred to a paper he had read before the Society in which he

dealt with drainage per rectum and vagina, and the use of an exploring syringe in certain cases.

Mr. O. L. ADDISON did not consider pelvic appendicitis more dangerous, or indeed as dangerous, as appendicitis elsewhere. Out of twenty such cases in which he had operated, about half of them being children, all recovered. He did not think obstruction so common as Mr. Handley's paper suggested, as not one of his cases was obstructed. He invariably found some history or evidence of disordered micturition, usually taking the form of retention or acute pain referred to the end of the penis.

Mr. W. MCADAM ECCLES considered that the appendix lay over the brim of the pelvis more commonly than was usually supposed, and more frequently so in the female than in the male. Pain felt before micturition implied a full bladder pressing, directly or indirectly, upon an inflamed appendix; while pain succeeding micturition implied an emptying bladder dragging upon an inflamed appendix. In a few cases he had seen retention, but only in males. Enuresis in children was sometimes due to an inflamed pelvic appendix. These symptoms were of much more value in chronic inflammations of the appendix. Mr. Handley's description of the condition of the ileum and lower part of the sigmoid in pelvic peritonitis was most instructive and his method of drainage most ingenious. With regard to a pelvic abscess slowly developing in connection with a chronically inflamed appendix he recalled a case in point: the abscess was opened above the symphysis as well as through the rectum, and the abscess cavity quickly closed.

Dr. A. J. RICE-OXLEY mentioned an acute case in which signs of vesical irritability led him to a correct diagnosis in an otherwise doubtful case. He was also able to support the statement that a very vague train of symptoms often ushered in an attack of appendicitis, which but for operation must have proved fatal. Early operation in most cases of anything like a suspicious character was the best way to deal with the attack.

Mr. SAMPSON HANDLEY, in replying to various points raised in the discussion on his paper, said that he thought some of the speakers had not drawn any distinction between true pelvic appendicitis—the subject of his paper—and cases where pus tracted into the pelvis from a normally placed appendix. The latter was a much less dangerous class of case, because it rarely led to obstruction.

THE NEW LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD DECEMBER 12TH, 1912.

The President, DR. P. S. ABRAHAM, in the Chair.

Dr. H. SAMUEL showed (1) a man from the clinic of University College Hospital, with lichen simplex chronicus (Vidal), affecting the lower parts of both legs. The condition had existed for about nine years, and there was considerable irritation. The left leg had been treated with salicylic plaster, and the right by means of the Kromayer mercury-vapour quartz lamp, and this one showed the greater improvement.

Dr. EDDOWES regarded these cases with much interest. He recalled a case treated with mercurial plaster, and mentioned that a gelatin dressing was one of the best applications for the mechanical prevention of injury from scratching. Internal treatment was also generally necessary.

(2) A little girl, *æt.* 7, with favus at the back of the neck, which was said to have followed a dog-bite. At first the lesions resembled those of tinea circinata, but the characteristic yellow scutula appeared and the fungus was identified. The scalp was free, but one lesion was present upon the right fore-arm. The child was of English nationality, but the mother stated that some foreign lodgers had been staying in the house.

Dr. NORMAN MEACHEN showed a young man, *æt.* 19, with a papillomatous growth upon the sole of the left foot, which had been present for fourteen years. There was occasionally a slight discharge. In addition,

there was a smaller, infiltrated lesion upon the inner side of the foot resembling a warty form of lupus. The father died of cancer, but there was no history of consumption in the family.

Dr. EDDOWES thought it was suspiciously like the verrucose form of cutaneous tuberculosis.

Dr. T. P. BEDDOES remarked upon the tendency of this class of case to give up treatment too soon.

The PRESIDENT said that he would scrape the growth freely and apply fuming nitric acid. These cases required very vigorous treatment.

Dr. DAVID WALSH showed a young man, *æt.* 23, from Dr. Meachen's clinic at Blackfriars, with ERYTHEMA PERNO ASSOCIATED WITH ARTERIO-SCLEROSIS.

He had suffered from chilblains all his life upon the feet, and since the age of fourteen upon his hands. There were no signs of heart disease, but he had large thick arteries, the brachial at the elbow being especially thickened and cord-like. He had nystagmus, which was a family trait. The urine was of 1035 sp. gr., but there was neither sugar nor albumin. He was a moderate smoker. The traumatic factor here was cold.

Dr. WALSH also showed a coloured drawing of the front of the knee of a woman, *æt.* 45, which presented a psoriatic patch. In this case passive congestion had been produced from the pressure of a tight garter, so that the condition was analogous to that caused by heart disease. With the removal of the garter the lesion rapidly got well.

Another drawing was shown of a patch of chronic dermatitis upon the leg, following traumatism associated with mitral disease.

Dr. VINRACE showed the patient with hypertrophic dermatitis upon the leg that he had exhibited at a meeting of the Society four months ago, in order to demonstrate the improvement that had followed simple shaving of the patch. The Wassermann test had been found positive. The localised keratosis had benefited greatly by the mechanical treatment in addition to internal medication.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD DECEMBER 13TH, 1912.

Dr. EDINGTON in the Chair.

Dr. T. K. MONRO reported on the last phase of the illness of a patient shown to the Society on May 3rd as subject of

SPLENOMEGALY, POLYCYTHÆMIA, INCREASED ARTERIAL TENSION, ARTERIO-SCLEROSIS, CARDIAC HYPERTROPHY, ALBUMINURIA AND GANGRENE.

Dr. J. H. TEACHER described the changes found at the autopsy, which were briefly: The heart was found to be considerably hypertrophied and the valves practically healthy. The lungs showed venous congestion, such as might be found in a mitral condition. The aorta was thickened and a number of patches of atheroma were present, but the importance of these was not noticed at that time. The abdomen seemed to be prominent. The spleen appeared to be large, but was not actually much increased in size, but hanging from it were great masses of adhesions, and the condition of the adhesions showed this to be an enormous increase in the blood vessels, and is really omental tissue wrapped round the spleen. On section the vessels are found not only to be veins but also arteries. This great mass of vessels in the omentum was connected with the diaphragm and the abdominal walls. In passing the finger between the liver and stomach, it was quite easy to make out the Foramen of Winslow, but you also felt a peculiar solid mass, which was thicker than the ridge of normal portal vessels, and a mass of tissue, forming a diamond-shaped area, with its apex at the Spigelian lobe, and practically a solid column in the centre of it with peculiar radiating matter round it, the rest of the diamond-shaped mass being cavernous tissue which was full of blood when fresh.

Further investigation confirmed the impression that it was a mass of venous channels, with the hepatic

artery quite clearly recognisable, and the stellate body at one end of the mass is one part of the portal vein which is thrombosed. The superior mesenteric vessels are represented by a bunch of veins, and the splenic vein it is rather difficult to say anything about, but it lies with the artery and seems quite solid, and it could not be traced properly to the spleen.

On section of the spleen there is a large infarction occupying the middle part of the organ and forming half of its whole bulk, and which gives the spleen its weight, probably under one pound but not actually weighed, and which is rather more than you would expect from simple cardiac congestion.

The renal vessels show extraordinary arterio-sclerosis, amounting to almost complete obstruction, a little beyond their origin from the aorta, and the kidneys show an extreme atrophy of the cortex right round the convexity, which becomes less towards the ends of the organ, and with a good deal of normal-looking tissue in the region between the pyramids. The surface of the organ is not cicatrised, but perfectly smooth, and has the appearance of normal atrophy.

There is a large patch of atheroma at the root of the aorta; there is no celiac axis artery to be found, but what appears is that the intercostals are hypertrophied. The superior mesenteric artery is completely blocked. The inferior mesenteric has nothing wrong with its orifice, but the trunk of it beyond the orifice is very large and wide, and following this trunk the hypertrophied vessel ran along in the omentum to the transverse colon, along the colon and eventually came down upon the superior mesenteric vessels a little beyond its origin; this inferior mesenteric appears to have conducted the whole circulation of the superior mesenteric and celiac axis.

The infarction of the spleen was very old, and occupied the centre, while the ends and some of the margins have escaped, and give the impression of being a thrombosis occurring in a very thrombosed splenic artery, with secondary thrombosis of splenic vein and spreading back to the portal system. The patient survived the thrombosis of the vessels, and the vessels became channelled and anastomosis formed. The case would appear to be one aptly described as being "a freak of arterio-sclerosis."

Dr. JOHN SHAW DUNN gave a short account of the
GRAWITZ TUMOUR OF THE KIDNEY,

and showed museum preparations, microscopic specimens, and lantern illustrations of the condition. He stated that renal tumours which are of clinical importance are not of great frequency, and in adult life the most important and most frequent is the Grawitz tumour, which was first described by Grawitz in 1885. These tumours are comparatively rare, and their structure is of considerable interest. The eleven cases under consideration were met with in the Western Infirmary during the past three years, and all, except one, were removed by operation. The symptoms complained of in six cases were swelling, in four it was pain, and there were six cases of hæmaturia. There was no very definite history of injury in any except one case.

It was noticeable that the age at which the tumour grew was rather advanced, the earliest being at 33 years of age, which seemed exceptional, while the youngest of the remainder was 47 and the next 56, and the others between 56-70 belonging to the late period of life.

The gross pathological appearances vary to some extent, the size varying from that of a large plum to a diameter of seven inches, but larger tumours are described. The situation of the tumour also varies to some extent, and of those under review four are in the upper pole of the kidney and two in the lower pole, three practically in the centre, and one case diffuse throughout the kidney and appears to have started in more than one place.

The appearance on section varies in accordance with the amount of hæmorrhage and necrosis which have taken place, and in all cases there is one well marked feature, which is a fairly bright and yellow colour, which is very characteristic and which suggests the character of the tumour when you cut into it. Necrosis may be seen in whitish, greyish or crumbled areas;

and rusty brown streaks are generally due to old hæmorrhage or altered blood pigment. In the older and slow-growing parts, bluish white patches of fibrous tissue which is often oedematous and hyaline. In one specimen necrosis had extended to some extent and had been followed by liquefaction, giving rise to a large cyst.

The degree of malignancy by any of them varies considerably. A large tumour may remain in its capsule, but on the other hand a small tumour may spread or give rise to metastases in the kidney. The spread is in the first place into the kidney, and may perforate the capsule, which is not usual, or may spread towards the pelvis of the kidney, which occurs rather frequently; for example, the six cases in which hæmaturia occurred. They may go into the renal vein, as has occurred in four of the specimens, and even spread into the inferior vena cava and give rise to blockage.

Metastases have occurred in only three of these cases, one in the liver and the lungs; and not infrequently the majority of metastases occur in the bones; in one of these cases the first complaint of the patient was swelling of the groin, which gave an impulse on coughing and fluctuation, and after being incised the necrotic tissue removed and examined, it was found to be a metastasis from the region of the pubic bone on the right side; afterwards a tumour was found in the upper pole of left kidney.

The histological characters are very striking in these cases, although the structure varies in different parts; the main feature is that the cells present a very considerable uniformity and peculiar characteristics; they are large cells as rule, with marked cell walls, and the protoplasm appears clear, as if it had been cleared out and replaced by transparent material. In frozen sections fat is found to be present, and often to a very considerable extent. There is also often present a large amount of doubly refractile material, which is probably cholesterolin, and glycogen is often found. The arrangements of the cells vary, they differ very markedly from the cells in the kidney; the kidney cells show granular protoplasm, which is dense in appearance and does not show hyaline characters. The peculiar nature of the cells which form the tumour gave rise to the early belief that they did not rise from the kidney and Grawitz thought they arose from aberrant suprarenal tissue, which is found under the capsule of the kidney, and most common towards the upper pole. This view held the field for a number of years, but recently it has been somewhat severely attacked, and Sturrock pointed out that though suprarenal cysts are most common in the upper pole, Grawitz tumour may be found anywhere. If they were suprarenal cysts why did they not occur earlier in life? Sturrock also brought positive evidence that the tumour might grow from renal tissue, and in metaplasia of renal cells in special cases, especially in cysts of granular kidney, in which the characteristics became those, and could not be distinguished from those, of Grawitz tumour cells.

From these and other facts they appear to be renal cancers.

Professor MUIR, Dr. MONRO KERR, Dr. TEACHER, Dr. A. YOUNG took part in the discussion which followed.

Dr. W. F. GIBB made a further report on the "tumour of the biceps muscle," described at the last meeting, and submitted a note by Dr. Joshua Ferguson on the histological findings, accompanied by microscopical sections from the tumour, and also sections from a tumour of allied character removed recently from the forearm.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, DECEMBER 12TH, 1912.

MR. ROBERT JONES in the Chair.

PATHOLOGICAL EVENING.

THE following specimens were shown and described:—

Dr. R. G. Wills: Cystic disease of the kidneys (ma).

Mr. K. W. Monsarrat: (1) Volvulus of the intestine associated with Meckel's Diverticulum (ma). (2) Pigmented endothelial malignant growth of the scalp.

Mr. R. W. Murray: Diverticula of the large bowel, with an explanation of the pathology.

Mr. Arthur Evans: (1) Subserous fibroid of cervix uteri; same specimen shows interstitial and submucous fibroid of the body of the uterus (ma) (2) Cystic kidney (ma).

Mr. Thelwall Thomas and Dr. Rees: (1) Carcinoma of the parotid in a woman *æt.* 34 (mi). (2) Papilloma of large intestine (ma and mi). (3) Spheroidal-celled carcinoma of the breast (mi).

Dr. Nathan Raw: (1) Secondary melanotic sarcoma of the liver. (2) Aneurysm of aorta which ruptured into the trachea.

Mr. Newbolt and Dr. McLellan: (1) Large mass of omentum removed from femoral hernia sac. (2) Fibrosarcoma of breast.

Mr. Douglas-Crawford and Dr. S. W. McLellan: (1) Fibrosarcoma of skin over the breast. (2) Duct carcinoma of breast (mi).

Mr. Armour and Dr. S. W. McLellan: Malignant breast; secondary deposits in glands of the neck (mi).

Dr. Buchanan and Professor Ernest Glynn: Tumour of brain simulating abscess.

Dr. John Hay: Ulcerative colitis.

Mr. Littler Jones and Professor Ernest Glynn: Congenital abscess of the mesentery with fatal volvulus of the small intestine

Mr. Kelly and Professor Ernest Glynn: (1) Fat necrosis in the great omentum in the neighbourhood of a perforated duodenal ulcer. (2) Fracture of the base of the skull causing pneumococcal meningitis.

Professor J. M. Beattie: (1) Endocarditis (4 cases) from rabbits. (2) Knee joint from a rabbit with chronic rheumatic changes—all produced by inoculation of a streptococcus isolated from cases of acute rheumatism.

Professor Beattie, Dr. Stookes, Mr. Murray, Mr. Thelwall Thomas, Dr. Hay, Professor Glynn, and Mr. Evans took part in the discussion of the specimens.

Mr. R. W. MURRAY read a note on the "Ætiology of Cysts" connected with hernia sacs.

Professor RUSHTON PARKER agreed with Mr. Murray. Mr. SIMPSON had met with a case in which there was a double sac.

Mr. THELWALL THOMAS thought cysts in association with hernial sacs were due to inflammatory affections.

Mr. MURRAY replied.

CENTRAL MIDWIVES' BOARD.

MEETING HELD THURSDAY, DECEMBER 19TH, 1912.

SIR FRANCIS CHAMPNEYS in the Chair.

THERE were also present Sir George Fordham, Dr. Briggs, Mr. Golding Bird, Dr. Herman, Miss Paget and Mr. Parker Young.

The only matter of particular interest dealt with related to the inquiries made by the Board some little time ago as to whether the

LYING-IN HOSPITALS AND LARGE MIDWIFERY TRAINING-SCHOOLS

in London would admit outside pupils to their lectures. The object was to reduce the number of small training-centres, and secure a high standard of teaching for all midwives. Queen Charlotte's, the City of London, the British Lying-in Hospitals and the Home for Mothers and Babies at Woolwich refused to admit outside pupils; the first two on the ground that while it might raise the standard of teaching for some, the general effect would be a levelling-down, as more candidates would avail themselves of the cheaper method of training—taking their practical work with an approved midwife in the districts only, and getting their lectures at the hospitals. This, of course, would mean a pecuniary loss to them. The British Lying-in Hospital made the excuse that it was shortly moving out of London, and the Home for Mothers and Babies declared it had not room at present for extra students; also, they feared it would be impossible to collect

outside pupils who would be willing to undertake the conditions of their training-school—viz., six or twelve months' training. The Clapham Maternity Hospital, the East-End Mothers' Home, the General Lying-in Hospital, Kensington Union Infirmary, and the New Hospital for Women, all agreed to admit outside pupils, many of them having done so already. The Chairman expressed regret that the four first-mentioned hospitals were not sufficiently public-spirited to assist the Board in its efforts to raise the standard of teaching, but, at any rate, they would now have five good centres in various parts of London.

Recognition as teacher was granted to Harold Wachter, M.R.C.S., L.R.C.P., and (*pro hac vice*) to David Ellis, M.D., B.S.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Dec. 21st, 1912.

THE FRIEDMANN TREATMENT OF TUBERCULOSIS.

AT the close of the meeting of the Medical Society of the 13th, Hr. Friedmann replied to the various speakers who had taken part in the discussion of the subject. He said there had been two classes of speakers—those who knew the results of his treatment and those who did not. With the exception of one case, due to a misunderstanding, all the gentlemen who had known the results of his treatment had confirmed what he had said. His preparation was one of tubercle bacilli that were naturally avirulent. No bacilli, human or bovine, had undergone any weakening process, so that nothing could return to an originally virulent state. He could, therefore, assure Hr. Citron that there was no fear that they could "return" to a virulent state. For the rest, he was of opinion that the principle for the treatment of tuberculosis by living and avirulent bacilli was the correct one, and the one that offered the best prospects. Hr. Klemperer, on the basis of his experiences with Koch's tuberculin, had concluded, both as investigator and physician, that tuberculin had neither curative nor immunising properties. The possibility that a single immunising injection in children might not have a life-long action, but that possibly it might have to be repeated, had been mentioned in his address; but whether immunity existed only so long as exciters were present in the system none of them knew, for even Hr. Klemperer was not convinced that we all carried the living exciters of small-pox along with us. He had never claimed to cure or to prevent mental diseases with his remedy; but he had pointed to a possibility that there was some "unexplained connection," and he would there say it again. When Hr. Klemperer said that there was nothing perfectly new in what he had brought forward, it must be placed against that that however interesting his experiments in treating cattle with human tubercle bacilli had been, he had never reported anything about the cure of human tuberculosis by living bacilli. In one great point—namely, that tuberculosis might be cured by suitable living bacilli—Hr. Klemperer agreed with him, and Robert Koch, as Hr. Klemperer had said, admitted the same thing when he said "It is only a question of finding a living bacillus that is avirulent, and that could be injected into the human subject." If Hr. Goldscheider wanted documentary evidence of the cure of tuberculous phthisis, he had to reply that the great amount of material that he had to report, and which grew daily, could neither be introduced within the limits of a short address nor in a newspaper was easy to be understood; but an accurate account would be given of every case of which a summary account had been given in a monograph that was being prepared. Naturally, in every individual case accurate determination of the clinical, and especially of the

physical, conditions would be given (diminution and clearing up of the dulness, gradual disappearance of the râles, etc.) by careful and numerous examinations of the expectoration. An account would be given of the disappearance of the tubercle bacilli. For that the method would be employed that he had described in Exc. Ehrlich's Encyclopædia of microscopical technique. In discussing hereditary disposition, also, this would be gone into thoroughly. It was a point that interested him deeply, in view of the former experiments he had made on animals regarding heredity. Hr. Kausch found the answer to his question whether tuberculous patients lost their fevers in his address: "Apart from grave mixed infections, the fever disappears very quickly." Hr. Meyer would not find in his address, as he believed he did, any denial regarding the action of tuberculin, as it was not his way to discredit remedies with which he had had no considerable personal experience. To dispute with Hr. Meyer as to whether a single injection would confer a life-long immunity, or whether the injection would have to be repeated once, was at present too early. Hr. Meyer's objection to immune injection from an ethical ground was, considering the opinions given by all the gentlemen who had a personal knowledge of his method, simply a phrase. If Hr. Wolff-Eisner doubted whether all the cases sent him by the gentlemen named in the address were really cases of active tuberculosis, and with that the diagnostic ability of all those gentlemen, he was spared any word of reply. From Hr. Piorkowski's interesting communication it appeared that his tortoise culture had the same or similar properties as his own weakly virulent tortoise culture (publication 1903). As he had said, that strain was useless for the human subject. When Hr. Bier conceded a curative effect, but said that he had not yet seen any decisive proof, he might be permitted to say that several of the cases shown had been sent him either by Hr. Bier himself or by his assistants. For example, Hr. Bier, in regard to the case of severe tuberculosis of the bones and skin which had not been operated on, had declared, "If this case is cured, it will be decisive proof." It was cured after three injections, without any other treatment. There was a Röntgenograph in the surgical klinik. In another also unoperated case there was a large spina ventosa of the great toe, which healed within six months without curetting. If Hr. Bier now said that he had never seen a closed fungus influenced by his treatment, he must reply that Hr. Bier had never sent him a case of closed fungus disease. The little girl shown, a child of eight, had such a closed fungus. For three months the limb was immovable. Even after a stay in Nordeney she could not walk a step, and had to be carried to Karfunkel's polyklinik. Five days after a simultaneous injection—the rapid effect was due to the intravenous injection—she walked to the polyklinik. The circumference of the knee had permanently diminished, as in another case of grave fungoid disease of the knee joint described to them by Prof. Müller. He would show the patient again later on. If Hr. Bier now said that tuberculous fistulæ occasionally healed of themselves, he might be permitted to reply that the girl of 19 whom they had seen, and who had had a fistula for 18 years, had not been cured in spite of every kind of treatment, but had been some months after the application of his treatment. Further, Hr. Geheimrat Bier had seen the ward sister with the progressive severe tuberculosis of the soft parts of the hand. Hr. Blaschko had sent him the case as an experimentum crucis, and had spoken of it at the previous meeting as "absolutely surprising." The case was not quite healed—the time was too short; it also would be shown later on. Regarding the statements of Hr. Schwenk, he had to say that all the injections in his case were made at a date before that when simultaneous injections were begun, and where inefficient resorption took place in consequence of a secreting weeping infiltration. Hr. Schwenk told him on July 20th, 1911, that certain ulcerations of the bladder had healed. It was plain that they must have reopened in consequence of some abscess forma-

tion. The patient was then inaccessible to him for a long time; the injections made the present year were simply for diagnostic purposes and were of tuberculin. The remark of Hr. Schwenk that he (the speaker) had asked for a favourable criticism collapsed completely, for Hr. Schwenk said not only to himself but also to Hr. Karfunkel that he had seen a favourable effect in both of the cases spoken of, but that through "stage fright" he would not say so in public. Hr. Schwenk was wrong also in saying that the case dated from 1911; it was a 1910 case of a period when both *technique* and dosage were imperfect.

Now for a few words in conclusion. He himself, although he had busied himself almost exclusively with tuberculosis for the last 14 years, had doubted and could not believe that the progressive improvements and recoveries related could last. His scepticism also melted away only gradually as in the cases of other gentlemen who had seen the work. They must accustom themselves to the thought and live into the thought of treating tuberculosis by living and uninjured curative material. Naturally they would be convinced of the success as regarded treatment before they did as regarded immunity. In regard to protective injection they would first of all notice how well all these children developed and how they thrived. When through the course of years the efficacy of protective injection had been proved, then immunisation would be proceeded with, but to a much larger extent. The curative effects they would soon confirm for themselves, and then they would be as much surprised and delighted as he was himself.

After the meeting Hr. Friedmann announced that as soon as possible the remedy would be procurable for all and that he would not give any preference to anyone.

AUSTRIA.

Vienna, Dec. 21st, 1912.

DUODENAL ULCERS.

At the Gesellschaft für Innere Medizin, Jonas presented a patient, æt. 28, who had complained for a year and a half of great weekly intermitting pain in the left side below the ribs, radiating towards the umbilicus, and sometimes into the right side as a dull cramping pain, particularly three or four hours after food, especially dry food. He never felt hungry, nor was he troubled with vomiting; the stools were slimy, but no blood; tenderness on pressure over the painful parts mentioned above, as well as the ileo-caecal region, but no pain posteriorly. We have now the differential diagnosis to make of this being an ulcer of the duodenum, a growth between the gall bladder and the stomach or duodenum, appendicitis chronica, or an ulcer in the small curvature of the pylorus, any of which it may be. The Röntgen examination gave a normal condition of the stomach. Rieder's test of six hours' rest gave about one-third of the meal left in the stomach, and the hepatic flexure had a half-moon appearance, with a horizontal or inferior portion of the duodenum filled. There was pain in the stomach when the lower bowel was pressed over the filled portion, but the organ was freely movable. According to Holzknacht, filling of the duodenum is associated with stenosis, and in this case the lower portion of the duodenum would come under that category in a slight form. To decide whether this stenosis is organic or spasmodic—that is, whether it is due to a cicatrix or a tumour, or was simply nervous in character—we must accept Oser's diagnosis for ulceration of the stomach, as pure nervous spasm in the duodenum is unknown. If the pain is removed with milk diet, and the Röntgen rays show a relief of the accumulation in the duodenum and also in the stomach after six hours' rest, it may be accepted as spasmodic, but in this case the duodenum was not altogether clear, and therefore it may be assumed that a spastic and organic condition is existing. In the case of milk diet, the bowel should be clear if not organic or a simple ulcer is present, as the removal of the irritation would at once relieve the spasm, and the distant part in the duodenum by a

reflex action would be at once cleared. If there happen to be a combination, however, of organic and spasmodic conditions, the milk diet test and the rest will remove the spasm, but the organic stricture will still remain.

Ortner remarked that these rules for diagnosis were not altogether to be relied upon, but might be accepted as a general guide. He had met with several cases where simple spasm of the bowel would not yield to narcosis.

BENZOL TREATMENT OF LEUCÆMIA.

Prof. Schlesinger presented a patient, æt. 53, who had, on entering hospital, 975,000 erythrocytes and 120,000 white blood corpuscles, 95 per cent. of which were mononuclear, the rest, or other 5 per cent., were polymorphic or neutrophile leucocytes. There was no bone marrow element nor nuclear red blood corpuscles. Benzol was given at first, in 30 drop doses, and increased later to $\frac{1}{2}$ -gramme doses in capsules, till she was taking 3 grammes of the drug daily. The leucocytes increased at first to 160,000, then gradually fell till they were 11,000 in the tenth week after treatment commenced. The red blood corpuscles at once rose from 975,000 to 3,700,000. The benzol treatment resembles the Röntgen therapy, but the general feeling is more comfortable. The œdema rapidly disappeared and the patient could leave her bed with ease.

Falta said he had the same patient under him some time ago. She had then 1,000,000 red blood corpuscles, with 20 per cent. of hæmoglobin, 250 leucocytes, of which 80 per cent. were small lymphocytes. After six injections of mesothorium the leucocytes fell to 54,000.

Eppinger was in favour of the benzol treatment for myeloid leucæmia. He recorded patients with 200,000 white blood corpuscles and 50 per cent. myelocytes. After four weeks' treatment with benzol the number of white corpuscles fell to 6,000, with 10 per cent. of myelocytes. He preferred prescribing the drug in gelodura capsules.

HUNGARY.

Budapest, Dec. 21st, 1912.

At the recent meeting of the Budapest Royal Medical Society Dr. Vlesinger read a paper on

ANGINA PECTORIS.

He emphasised the importance of rest in bed as the most effective measure in the treatment of angina pectoris. It acts by reducing the arterial tension, while it is a tonic for the heart and reduces its excitability. In order to have the maximum effect, the patient should be kept in bed for from two weeks to two months, the diet being restricted at first to water, and milk, gruels, etc., being gradually allowed. The rest in bed should be supplemented with the usual drugs. Nothing can compare in efficacy, he says, with simple rest in bed; the benefit is most apparent in the elderly and those inclined to corpulence who fall off a little in weight. Patients may be classed as (1), those whose arterial tension during the pain keeps normal or below—repose does not modify it; (2), those in whom the tension is high and is not influenced by repose—this is very rare; (3), those in whom the arterial tension subsides under the influence of the rest in bed—this is the rule in two-thirds of all the cases; (4), those in whom the tension does not subside, but even increases during repose, although the pain does not increase. Among twenty patients from 75 to 73 years old with angina pectoris, he found three with normal or low arterial tension. The tension was unmodified by repose in three other cases, but the pains subsided, showing that the tension was not the cause of the pains during effort. In several other cases the rest in bed reduced the arterial tension at once. One patient was a man of 67 with maximal tension of 28 (Hicks) during an attack. Under bed rest, ice to the heart, restriction of his food to water and milk, and three injections of two milligram morphine, the tension dropped to 19 and the patient felt like a new man. Another patient had long been having attacks of angina pectoris at the slightest

effort. A course of rest in bed and restriction to a milk diet with a loss of about 14 pounds in weight restored normal conditions to such an extent that he has been in good health during the eight years since to date, with no recurrence of the angina pectoris. Coronary lesions are not encountered in every case; the aorta or the myocardium may be involved rather than the coronaries. Bed rest is least effectual, Vlesinger added, in case of concomitant aortic insufficiency.

ARTIFICIAL REDUCTION OF THE CIRCULATION AS A THERAPEUTIC MEASURE.

Dr. Hasenfeld applied the shutting off a part of the circulation as a therapeutic measure in a number of cases, on Klapp's and Tornai's suggestion, by applying a constricting band on the limbs for twenty or thirty minutes every morning for a week or so. The effect was striking, he reports, in cases of fatigue and dilatation from stasis of the right heart, the right ventricle being too weak to empty itself completely during the systole. By holding back part of the blood, the right ventricle was able to accomplish its task better, with less expenditure of energy, and was given a chance for rapid recuperation. The most striking benefit was obtained with mitral affections, but benefit was also realised even with degeneration of the myocardium and with beer heart (Bier Herz), the tachycardia, arrhythmia and insufficient systole subsiding. After release from the constriction the pulse becomes slower and more regular. In the severer cases in which heart tonics fail, little can be expected from the constriction method, but he has obtained good results in a few exceptional cases even of this kind. The relief from the measure is so great that often these patients await its application with impatience. Diuresis is generally promoted, and there was profuse sweating in some cases, as the constricting bands were removed; this must be done very slowly and gradually. He uses rubber tubing for the constricting band as for the Homburg technic. He attempted to enhance the action of drugs by this means, finding that a small amount had an immeasurably greater effect when the limbs were excluded from the circulation, but in order to accomplish this the arterial circulation in the limbs had to be arrested likewise, and the constriction kept up for an hour or more; the patients objected to this, so he has abandoned the method.

CHRONIC GASTRITIS.

In cases of chronic gastritis Professor Stiller prescribes the following drugs for improving the appetite:

Tinct. chinæ comp.
Tinct. cort. aurantior, aa. 10.0 gm.
Tinct. nucis vomicæ, 1.00.
Tinct. rhei darelli, 4.00.

T.D.S.—Thrice daily, 15-20 drops.

R Herbar. galeopsidis grandifol.
Florum verbasci, aa. 20.0 gm.
Marubii albi.
Lichen islandic, aa. 10.0 gm.
N.f. species. Tea.

R Extr. fluid condurango, 30.0 gm.
T.D.S.—Thrice daily, 10-15 drops.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

A NEW CURE FOR TUBERCULOSIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have been much interested in reading your article under the above heading in your issue of November 13th, page 508. This new treatment appears to have only the authority of the lay press behind it so far. I wish to draw attention to a method of treatment introduced by an Irish medical man. He introduces a new theory upon "Shut away fluid,"

which, if he be correct, goes to show that no treatment can possibly cure 100 per cent. of pulmonary cases unless the surgeon and physician join hands in the treatment. The book (a) written by Dr. Minchin, of Dublin, contains valuable information which no medical man can afford to be ignorant of. I have adopted his treatment with allyl sulphide inhalations and his special inhaler for some years with gratifying results, and I have found it superior to any other treatment. It was only upon the recent appearance of Dr. Minchin's book that I thought of treating a localised lesion (the class of case in which he claims 100 per cent. of cures). I have only had one case so far, but it is so remarkable a cure that it leads me to support his claims. The case was that of a boy, æt. 18 years, who was delicate and tuberculous, and who had a large cold abscess on his back, which had existed for a considerable time. He was sent by an eminent Belfast physician to Rostrevor in the hope that the change would benefit his general health. This abscess had been treated by repeated aspiration, and his physician wrote asking me to continue this treatment, and certainly not to open it for fear of secondary infection. I aspirated a few times, but it filled up quickly. I asked Dr. Minchin if he thought allyl sulphide would cure it, and he replied, "Certainly; open it freely and apply the allyl sulphide emplastum, and it will surely be healed in about a month." I was spared the trouble of opening it, as it burst at one of the needle punctures. I tried various antiseptics, syringing, etc., three or more times daily, as the discharge was profuse. It got worse, and I applied the allyl sulphide emplastum, when the healing which took place was astonishing. There was not a drop of pus exuded, even on pressure, in a fortnight, and it healed perfectly. The boy, I may state, was also placed on the allyl sulphide inhalant, and his condition after six months is so far improved that he has discarded his bath chair, and now walks firmly and well. The lung trouble has for some time remained in abeyance; the cough, which was very troublesome, has ceased; and, indeed, I regard him as a most satisfactory case, and one likely to result in a permanent cure. I now approach any case of tuberculous lesion with confidence and hope.

I am, Sir, yours truly,

JOHN F. ELLIOTT, L.R.C.S.P.Irel.

Rostrevor, December 11th, 1912.

THE NATIONAL HEALTH INSURANCE COMMISSION AND SPECIAL PAYMENTS TO MEDICAL MEN.

The following correspondence has been sent us for publication by the Registrar of the General Medical Council:—

Offices: 299, Oxford Street, W.

December 13th, 1912.

To SIR ROBERT MORANT, K.C.B.,

Chairman of the National Health Insurance Commission (England), Buckingham Gate, S.W.

DEAR SIR,—My attention has been called by members of the National Health Insurance Act Committee of the General Medical Council, to an important point arising out of the National Health Insurance (administration of medical benefits) Regulations, 1912; and on behalf of the Committee I desire to submit the point to the Commissioners, in case they should desire to offer any official observation upon it.

Under the alternative forms of agreement, as between a Local Medical Committee and a practitioner on the panel, contained in Part II. of the First Schedule to the Regulations, it is provided in Forms B, C, D, and E that in respect of a given patient the practitioner is entitled to claim special payments for the following services: (a) "Surgical operation requiring local or general anæsthetic," and (b) "Administration of general anæsthetic for the purposes of any operation included under Medical benefit."

These provisions, taken together, are, by some of

my colleagues, understood to imply that both the payments in question can be claimed only in cases where the practitioner himself operates, and also administers the general anæsthetic; and that no payment can be claimed under (b) when the operating practitioner obtains the services of a qualified person to administer the anæsthetic to the patient.

On November 27th, 1909, the General Medical Council adopted the following Resolution:—

"That it is expedient in the public interest to provide that the person who administers the anæsthetic for the purpose of inducing unconsciousness during any medical, surgical or dental operation or procedure, should not be the person who performs the said operation or procedure, due provision being made for cases of emergency."

The specific question I desire to put to the Commissioners is this: May an operating practitioner under any of the forms of agreement marked B, C, D, and E, who acts in accordance with the foregoing Resolution of the Council, claim a separate payment in respect of the fee paid by him to another practitioner for administering the general anæsthetic?

I am, yours very faithfully,

(Sd.) DONALD MACALISTER,
President General Medical Council.
Buckingham Gate,
London, S.W.,
December 16th, 1912.

To THE PRESIDENT,

General Council of Medical Education and Registration of the United Kingdom.

DEAR SIR,—In reply to your letter of the 13th, I have the honour to say that the answer to the question in its concluding paragraph is in the affirmative: that is to say, under any of the systems B, C, D, or E referred to in your question, the practitioner who performed an operation (itself within the scope of medical benefit) and employed another practitioner to administer an anæsthetic, would be entitled to receive, out of the medical benefit fund, the stated fee for the anæsthetic, subject, of course, to such possible scaling down or up as under systems B, C, or E would apply to all such fees.

Under system A, the provision of the anæsthetic would be one of the services which the practitioner had contracted to render in consideration of the inclusive capitation fee, and he would, in those circumstances, have to pay the anæsthetist himself.

I am, yours truly,

ROBERT L. MORANT.

Chairman National Health Insurance Commission (England).

THE TRIUMPH OF QUACKERY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—During a career of more than twenty years as general practitioner and Poor Law Medical Officer, I have come across a great number of cases where valuable time has been lost through patients making use of quack remedies before consulting a medical practitioner, and many cases in which direct harm has been done by the use of these remedies. I can fully confirm Mr. Sewill's statements, but regret that, never thinking they would be needed, I have not kept accurate written records of the cases. The following are some of those I can recall, and of which I can furnish details:—Children and adults suffering from bronchitis, phthisis, and pneumonia, dosed with "lung tonics." Children, while "teething" and really suffering from improper feeding and indigestion, dosed with "soothing syrups." Pregnant women dosing themselves with pills advertised to "relieve irregularities," and causing acute diarrhœa and pain, and, in some cases, miscarriage. Constipation treated by large doses of advertised cathartics instead of regulation of diet and mild laxatives. Hernia treated by quacks, who sell high-priced trusses, which do not fit and which are injurious. Money wasted on the much-advertised sham tonics containing alcohol, instead of being spent on good nourishment. Cases of phthisis treated by "lung

(a) "The Treatment, Prevention and Cure of Tuberculosis and Lupus with Allyl Sulphide." By Wm. C. Minchin, M.D. London: Balliere, Tindall, and Cox. 1911.

tonics" and no proper precautions taken as to isolation and disposal of sputum. Cases of chronic nephritis treated with "kidney pills," and no attempt made to regulate diet, etc. Cases of rheumatoid arthritis treated by "anti-rheumatic rings." Cases of "skin disease," sometimes being syphilis, treated by blood medicines, which have no effect. Cancer cases treated by quack remedies till they were past operation. Wounds treated by quack ointments becoming dangerously septic. Ulcers of the cornea treated by eye ointments until intense inflammation supervened and the sight was threatened.

I offered to give evidence before the Select Committee, and may yet be called.

I am, Sir, yours truly,

POOR LAW OFFICER.

REFLEX STIMULATION OF THE VAGUS CENTRE IN TREATMENT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I cannot be the only one of my class—clinical teachers—who will have read with interest the letters on the above subject, contributed to your current issue, respectively, by Dr. Midelton and Dr. Hamilton. I trust they will not consider it in either sense of the word impertinent if I remark that the quality of their writings in itself commands respect. I should be glad to see a more lengthy communication from either or both of them. I shall certainly make trial of the treatment they describe in suitable cases, and shall hope to report the results in due course in your pages. It is a treatment that at least can do no harm. If it is useful the fact ought to be capable of demonstration; the number of cases to which it can be applied is so great. It is, of course, only when a similar reaction takes place in an overwhelming majority of instances that we can begin to put the treatment and the cure in relation as cause and effect. I cannot suggest any rationale of the process. Explanation seems so difficult that scepticism is not only justifiable but even called for. But this does not forbid a trial; it ought only to ensure that the experiments will be carried out with the most rigorous possible scientific exactitude.

I am, Sir, yours truly,

December 20. M.D., F.R.C.P.

OBITUARY.

DR. C. T. WILLIAMS, OF LONDON.

WE deeply regret to record the death of Dr. Charles Theodore Williams, M.V.O., which took place on the 15th inst., at his house in Upper Brook Street, W. The deceased, who was born in 1838, was the son of the late Dr. C. J. B. Williams, F.R.S., Physician Extraordinary to Queen Victoria. He was educated at Harrow, and graduated at Pembroke College, Oxford, with honours in natural science. He continued his professional studies at St. George's Hospital, and also in Paris, becoming M.D. in 1860, and F.R.C.P.Lond. in 1871. From 1866 onwards for some years he held various offices, such as demonstrator of anatomy and physiology at St. George's Hospital, and assistant physician to Brompton Hospital, receiving the appointment of physician at the latter institution in 1871. He was a member of and, in due course, presided over many medical bodies, and was ever ready with advice and, when needful, financial assistance for them. His college at Oxford (where he founded scholarships in human anatomy and physiology and two in pathology, including bacteriology, in relation to medicine elected him an Honorary Fellow in 1907, and he was also hon. treasurer of the Royal Meteorological Society. Dr. Williams belonged to a large number of foreign medical associations. He was physician to the English and Scottish Law Life Assurance Office.

From an early period in his career Dr. Williams gave special attention to the effects of climate, especially at

high altitudes, on tubercular complaints. He claimed, in delivering the Harveian Oration at the Royal College of Physicians in 1911, to have personally studied the climates most advantageous for the treatment of consumption all over the world, and to have recorded the effects on over 400 of his private patients. He devoted special care to the investigation of the result of diminished barometric pressure, the diathermic properties of the air, and its freedom from pathogenic germs at high altitudes. He held that professional investigation and popular education were imperatively necessary in the crusade against tuberculosis, and, of course, emphasised the need for early diagnosis and treatment. He took part in many international and other congresses and was a vice-president of the International Anti-Tuberculosis Association. He also acted as physician of the King Edward VII. Sanatorium, and was made a member of the Victorian Order in 1906. His contributions to medical literature included one on "Pulmonary Tuberculosis: Its Arrest, Treatment and Duration," and over 100 papers on his special subjects.

He married, in 1868, Mary, second daughter of the late Mr. J. Gwyn Jeffreys, F.R.S., and was a member of the Athenæum Club.

DR. GEORGE GRIFFITH, J.P.

THE death took place on the 16th inst., at his residence at Milford Haven, of Dr. George Griffith, J.P., ex-chairman of the Pembrokeshire County Council. The deceased, who qualified M.R.C.S.Eng. and L.S.A. Lond. in 1861, was educated at the Normal College, Swansea, and Guy's Hospital. He became M.R.C.P. Edin. in 1874. After qualification, he opened a practice at Haverfordwest, but afterwards removed to Milford Haven, succeeding the late Dr. Field as District Medical Officer for the Haverfordwest Union. This appointment he held until a few years ago, when, on his retirement, his son, Dr. W. S. Griffith, was appointed in his stead.

Dr. Griffith was the first member to represent Milford Haven on the Pembrokeshire County Council, and for three successive years he was chairman. He had also served on the Standing Joint Committee, the Education Committee (being Chairman of the Building Sub-Committee), the now defunct School Board of Milford, of which he was the first and last Chairman, the County Governing Body, the Milford County School Managers, of which he was chairman, and the Haverfordwest Grammar School Governors. He had occupied the position of Chairman of the Pembrokeshire Small Holdings Committee, the County Association (Territorial forces), Pembrokeshire Old-age Pensions Committee, and the Joint Counties' Asylum Committee.

Advancing years brought him additional public work, but amidst it all he found time to take a keen and active interest in politics. He was chairman of the Pembrokeshire Liberal Three Hundred in succession to the late Lord Kensington, as well as Chairman to the Pembroke and Haverfordwest Boroughs Liberal Association. Though he belonged to a family of staunch Nonconformists, he was himself a Churchman, and at one time he held the office of churchwarden at Steynton. Dr. Griffith had the distinction of having saved Mr. Lloyd George's life. Shortly before the death of the Chancellor's brother at Bullford Farm, Steynton, the infant which was destined to rise to such a high position in the councils of the nation had a severe attack of croup, and the life of the child, then only just a year old, was despaired of. In one of his sketches of Mr. Lloyd George's life, Mr. Hugh Edwards, M.P., has the following reference to the matter:—"A messenger was hastily despatched through sleet and snow to the neighbouring town in quest of the doctor. The doctor—a young man fresh from the hospital—hastened back just in time to administer the necessary relief. He devoted himself to the case with a skill and an assiduity that left nothing to chance. He had his reward; there came a turn for the better, and the life of the child was saved."

MEDICAL NEWS IN BRIEF.

The Scottish Medical Colleges and the Insurance Acts

A CIRCULAR has just been issued to the medical profession of Scotland, signed by the Presidents of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. The circular states that the chief aim of the "Seven cardinal principles" was to maintain and extend the freedom of the profession from lay control in the conduct of its professional duties. Neither in the Insurance Act itself, nor in the provisional regulations issued by the Commission, have these demands been fully conceded. If members of the profession in Scotland are satisfied with such minor concessions as have been promised, and if they are prepared to accept service under local Insurance Committees on the terms indicated, the Royal Colleges and the Royal Faculty, while not attempting to dissuade them, cannot be parties to an agreement which is derogatory to the status of the profession in the view of the Colleges and the Faculty. The Act will perpetuate and extend some of the worst features of club practice. The Royal Colleges and the Royal Faculty are assured that many practitioners throughout Scotland believe with them that the Act is still derogatory to the profession, and they wish it to be understood that the profession, in adhering to that view, may count on their sympathy and support.

A New London Cancer Institute.

A NEW cancer institute has just been established at the Brompton Cancer Hospital, at a cost of some £6,000. The importance of X-rays and other electrical methods in the treatment of malignant disease is now fully recognised, and the Institute has in its possession an excellent equipment for this branch of therapeutics. It is a two-storeyed building furnished with the finest apparatus for X-ray examination, photographs, and treatment that it is possible to obtain, and contains the most powerful X-ray coil in the country. Complete protection has been provided for the doctors, the powerful generators being enclosed in thick lead screens. Only a small window is left through which the rays used for treatment can be passed and focussed, and both the X-ray tube and the patient are shut off in cabinets with lead-glass screens through which the doctor can watch the progress of the treatment.

Surrey Doctors and School Clinics.

At a meeting of the Surrey Education Committee at Kingston last week, it was reported that a meeting of county medical men had been held to consider the proposed establishment of school clinics with whole-time doctors and dentists at a cost of £10,000 a year to the county. A resolution was adopted at the meeting in which it was declared that the treatment of defective school children could be efficiently carried out by the local practitioners, acting as part-time Medical Officers to the proposed clinics of the areas in which they reside, and that the medical practitioners of Surrey were prepared to form a committee to co-operate with the Surrey County Council and discuss a modification of the scheme under consideration. The Education Committee agreed to discuss the matter with the representatives of the doctors.

The Compulsory Notification of Non-Pulmonary Tuberculosis

New Regulations were issued by the Local Government Board last week to the effect that non-pulmonary tuberculosis will be included in the list of compulsorily notifiable diseases from February 1st, 1913.

It is pointed out by the Board that more than half the deaths from that complaint are of children under five years of age, and the hope is expressed that notification may tend to secure an improvement in the conditions under which the children live.

University of London.

THE following have passed the M.D. examination for internal and external students—

Medicine.—J. D. Benjafield, B.S., and R. L. Crabb, B.S., Univ. Coll. Hosp.; E. H. A. Pask, B.S., Univ. of Sheffield; R. Phillips, B.S., Middlesex Hosp.;

H. F. Renton, B.S., Guy's and Univ. of Leeds; A. L. Robinson, B.S., H. L. Tasker, B.S., and F. M. R. Walshe, B.S., B.Sc., Univ. Coll. Hosp.; T. H. Whittington, King's Coll. Hosp.; T. H. Woodfield, St. Bartholomew's.

Midwifery and Diseases of Women.—G. Dunderdale, B.S., and T. Evans, B.S., Guy's; C. R. Hoskyn, St. Bartholomew's; R. Stout, B.S., Guy's.

Tropical Medicine.—W. Gillitt, Middlesex Hosp. and London Sch. of Trop. Med.

M.S. Examination.—Surgery.—W. Gilliatt, M.D., Middlesex Hosp.; S. L. Graham, Univ. Coll. and London Hosp. and Univ. of Birm.; E. G. Stanley, St. Bartholomew's.

University of Cambridge.

AT a Congregation held on December 19th the following degrees were conferred—

M.D.—B. Day and (by proxy) R. A. P. Hill, Caius; F. S. Scales, Jesus.

M.B. and B.C.—T. H. Just, Trinity; H. T. Depree, Clare.

M.B.—J. W. Dew, Clare.

B.C.—G. V. Bakewell, Clare.

Examination for Medical and Surgical Degrees.—The following have now satisfied the examiners in all three sections:—F. S. Adams, Christ's; J. W. Adams and H. C. Attwood, Caius; T. E. Banister, Christ's. H. W. Barnes, Jesus; F. S. Bedale, Clare; E. Calvert, Joh.; W. T. Channing-Pearce, Emm.; D. G. Cherrington, Trin.; A. C. Clifford, Emm.; H. J. Couchman, Caius; H. G. Earle, Down.; J. V. Fiddian, Emm.; E. C. Hardwick, Corp.; T. L. Hardy, Selwyn; I. W. Joynt, Emm.; W. C. D. Maile, Pemb.; C. G. H. Morse, Emm.; H. J. S. Morton, Trin.; T. H. Oliver, Caius; T. E. Osmond and G. M. Parker, Emm.; S. H. Rouquette, King's; L. T. Rutherford, Clare; A. S. Seabrooke, Christ's; F. B. Smith, King's; G. W. Spencer, Joh.; F. S. Tinker, Pemb.; J. W. Tonks, Caius; C. Warner, Pemb.; A. M. Zamora, Christ's.

University of Edinburgh.

THE following degrees were conferred on December 18th:—

M.D.—J. W. H. Babington (Capt. I.M.S.), M.B., Ch.B., G. Bidie (Major, I.M.S.), M.B., C.M., W. L. Burgess, M.B., Ch.B. (with first-class honours), C. C. Iles, New Zealand, M.B., Ch.B., A. J. B. Leckie, M.B., Ch.B., R. V. Morrison (Lieut. I.M.S.), M.B., Ch.B., A. H. Rutherford, Australia, M.B., C.M., Jessie A. Scott, New Zealand, M.B., Ch.B., E. A. Walker, M.B., Ch.B.

Seventy-nine candidates received the M.B., Ch.B., and one the M.B., C.M.

N. H. Bolton, M.B., Ch.B., received the Diploma in Tropical Medicine and Hygiene.

The following candidates have passed in Anatomy of the Second Professional examination:—John S. Armstrong, James G. L. Brown, Alexander F. Campbell, Arthur G. Clark, Andrew Clark, John R. Crolius, David Dunlop, Harry F. Ferguson, George W. M. Findlay, Bhaskar B. Gadgil, Francis M. Halley, Basil Haskins, John A. Henderson, Tanguturi Janakiramiah, Frederick J. C. Johnstone, C. W. S. Davies Jones, Muriel H. Kerr, J. Etienne Larche, Harry Lewis, George A. Macdonald, Alfred L. M'Ilwaine, John Macqueen, John W. Malcolm, Charles E. Meryon, Terence C. St. C. Morton, Ronald N. Phease, Owen D. Price, Norman L. Reis, Charles Resnekov, John W. Riddoch, A. J. Desmond Rowan, Cedric Russell, Joseph H. M. Sandison, George Schussler, Maung Sett, George H. Sinclair, Herbert S. Smith, Robert B. Stewart, Thomas M. J. Stewart, Alexander J. Taylor, Guy M. Torrance, Andre F. de Waal, William Waddell, Chik H. Wan, Lloyd H. Werden, B.A., John D. Whitfield, Maurice E. Willcock, Margaret K. J. Wright.

University of Liverpool.

THE following have qualified for the diploma in Tropical Medicine:—Lillie E. Dunn, M.B., B.Ch., C. Hardwicke, M.D., J. R. Jagose, L.M.S., M. N. Mitra, L.M.S., C. D. Myles, M.B., Ch.B., H. Seddon, M.B., Ch.B., J. Smalley, M.B., Ch.B., P. C. H. Strickland, M.R.C.S., L.R.C.P., and W. R. Watson, M.B., B.Ch.

SUMMARY OF RECENT MEDICAL LITERATURE ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Ventrofixation and Subsequent Pregnancies.—Fergusson (*Jnl. Obs. and Gyn. Brit. Emp.*, xxii., 3), gives an extensive review of the many operations and modifications for the replacement of retroverted uteri. He considers that the operation is used very often in this country when its use is not absolutely necessary; and even in the most suitable cases for suspension—*i.e.*, pure retroversion—one should be reticent in advising or performing the operation until all other methods have been given a trial. He advises proper reduction under an anæsthetic, and the fitting of as large a Hodge pessary as the vagina will hold comfortably, this to be reduced in size every three months until the uterus retains its normal position without support. When the vaginal outlet is very lax and the pessary tends to come out, it is advisable to repair the perinæum and then begin pessary treatment. The choice of operation lies between Kelly's suspension, Gilliam's operation or one of its modifications, and ventrofixation with sterilisation. This latter should be reserved for women almost at the menopause. Gilliam's operation is more troublesome than Kelly's, and has not been as well tested in its relation to subsequent pregnancies. The reported cases of dystocia after Kelly's suspension are largely discounted, and most of the cases, on being carefully looked into, suggest faulty nomenclature or procedure, or an immediate after history suggestive of septic infection of the wound, possibly very slight. F.

Effects of Ureteral Ligature.—Barney (*Surg., Gyn., and Obs.*, xv., 3) during the past three years has been carrying on experimental work, and has sought to compare his results with those of similar procedures in man. The statements in text-books are conflicting and largely erroneous. He has collected 46 cases of unilateral and 16 of bilateral sudden and complete occlusion of the ureter. The accident produced no immediate symptom whatever except anuria (in the double occlusion cases). In 26 cases, or 41 per cent., of the unilateral cases there was no immediate or remote symptom, but these cases were not followed long enough to give finality, except one who died nine months later of recurrent malignant disease. Anuria only occurred once in the cases of unilateral injury, and this is entirely in accord with the experimental results. In the bilateral cases anuria was the only symptom, and in no case was it allowed to continue for more than 96 hours. In this case, and in one of 48 hours' duration, nephrotomy was performed, and both cases ended fatally. In the others continuity was restored with a mortality of 33 per cent., but the suppression of urine could not be looked upon as alone the cause of death. He concludes that both ureters may be clamped for as long as 72 hours with complete recovery after removal of the obstruction, and one ureter may remain tied for ten days without destroying the integrity of the kidney. Hydronephrosis was observed in 80 per cent. of cases, and was always of moderate size. In the remainder there was said to be no change in the kidney. In unilateral cases the death-rate was 17.8 per cent., but other factors had to be taken into account. Examination by cystoscope might be the only means of diagnosis. F.

Experimental Hydronephrosis.—Scott (*Surg., Gyn., and Obs.*, xv., 3) studied the effects of complete and incomplete ligation of the ureter upon the kidney. It is stated, especially by English and American authorities, that a sudden complete obstruction of the ureter produces atrophy of the kidney, with little or no dilatation of the pelvis, but that an incomplete obstruction produces hydronephrosis of great degree. This statement is wholly controverted by the results

of experiments. Complete ligation produced hydronephrosis of degree depending on the duration. The changes in the kidney parenchyma take place in a definite order. Compensatory circulation of the renal vessels probably plays no part in determining atrophy or hydronephrosis. Incomplete obstruction produced hydronephrosis of degree depending upon the amount of force required to overcome the obstruction and the duration. Complete obstruction produced hydronephrosis more rapidly than incomplete, and the microscopic changes are practically the same under both circumstances. Complete obstruction retarded secretion, but did not arrest it. Even in the highest degrees the kidney epithelium is never completely destroyed, but is capable of further secretion. Atrophy did occur in one case of incomplete obstruction, but was not produced by complete permanent obstruction. F.

Two Cases of Peptic Ulcer of the Œsophagus.—Watson (*Brit. Med. Jour.*, November 21st, 1912) reports two cases, both of which occurred in males and both ended fatally. The first patient was admitted to hospital about four hours after the commencement of epigastric pain, with symptoms of acute abdomen. At the laparotomy, half an hour later, no free gas or fluid was found, intestines were red and injected, and there were small omental hæmorrhages. The remaining abdominal organs showed no lesions. The stomach was washed out on the table, but only a small portion of the fluid was returned on siphonage. There was no vomiting. The patient became very restless, respirations increased in rapidity, and the patient died eight hours later. At the autopsy the right pleura was found to contain about a pint of blood-stained fluid, the left about four pints of thick, turbid brown fluid, with the odour of gastric contents, and containing pieces of meat and vegetables. Both lungs were collapsed. In the lower lobe of the left lung, near the middle line, there was a small gangrenous cavity, which communicated by an aperture about $\frac{3}{8}$ in. in diameter with the left pleural cavity, and by a similar-sized orifice with the œsophagus immediately above the cardiac opening of the stomach. The œsophageal rupture showed no chronic ulceration or new growth and the rest of the œsophagus was normal, as was also the stomach. There was no peritonitis. The second patient complained of sickness after food for five months. There was occasionally coffee-ground vomit. Last two months there was constant epigastric pain, and tenderness to the left of ensiform cartilage. As pain and vomiting continued after five weeks' treatment, laparotomy was performed, and nothing abnormal found. Patient died two days later. At the autopsy the stomach was found normal, and there was no peritonitis. There was a chronic punched-out ulcer, the size of half-a-crown, involving the lower end of the œsophagus close up to the cardiac orifice. There was no perforation into the pleural cavity, but the base of the ulcer was extremely thin. The microscope showed chronic inflammation and no evidence of malignant disease. S.

Report on the Treatment of Simple Fractures.—The Report of the Committee of the British Medical Association on the Treatment of Fractures (*Brit. Med. Jour.*, November 30th, 1912) is based on over 2,000 cases examined at general hospitals in England, Ireland, and Scotland, and deals only with simple fractures of the shafts of long bones. The Committee finds that in children under 15 years the results obtained by non-operative treatment are unlikely to be improved upon materially by any other method. Non-operative cases (1,017) 90.5 per cent. good functional results; operative cases (64) 93.6 per cent.

good functional results. In non-operative cases of fracture of both bones of the forearm the results are not good. In comparison with the non-operative results in children the result of this treatment in those past childhood is not satisfactory, and the older the patient the worse the result. In cases treated by immediate operation, the deleterious influence of age on the functional result is less marked. In nearly all age groups, operative cases show a higher percentage of good results than non-operative cases. Although the functional result may be good with an indifferent anatomical result, the most certain way to obtain a good functional result is to secure a good anatomical result. No method which does not promise a good anatomical result should be accepted as a method of choice. For this reason mobilisation and massage by themselves have not been found to secure a high percentage of good results, though they are valuable supplementary methods of treatment. Of operative measures, those which secure reposition and absolute fixation of the fragments yield better results than methods which fall short of this. Imperfect fixation by wires and sutures is unsatisfactory except in the case of the olecranon process of the ulna. In order to secure the most satisfactory results from operative treatment, it should be resorted to as soon after the accident as possible. When employed in consequence of failure of non-operative measures, the results compare very unfavourably with those of immediate operation. Skill, experience and strict asepsis are absolutely essential for good results in operative treatment; most failures are due to infection of the wound. The mortality directly due to the operative treatment of simple fractures of the long bones has been found to be so small that it cannot be urged as a sufficient reason against operative treatment. In general practice the non-operative procedures are likely to remain for some time yet the more safe and serviceable.

S.

Excretion of Formaldehyde by Patients taking Urotropin.—L'Espérance (*Boston Med. and Surg. Journ.*, October 24th, 1912) relates the results of a study he has made on this subject, using Burnam's test. This test is performed as follows:—"To about 10 c.c. of suspected urine in a test-tube at body temperature is added (1) of solution phenylhydrazine HCl 0.5 per cent. gts. 111; (2) solution sodium nitroprusside 5 per cent. gts. 111; (3) of saturated solution sodium hydrate a few drops poured along the side of the test-tube. As this latter solution diffuses throughout the urine in the tube, if formaldehyde is present a deep purplish-black colour is seen, quickly changing to dark green, gradually getting of a lighter shade of the same colour, to, finally, pale yellow." In the absence of formaldehyde, on the addition of the sodium hydrate solution the urine turns to a reddish colour and then to a light yellow. This test the author has found to be trustworthy, and is quickly and easily performed. Investigation has shown that formaldehyde, to be of any use as a urinary antiseptic, must be present in the urine in a strength of at least one part in six thousand. Burnam's test applied to the urine of 250 patients taking urotropin showed the presence of formaldehyde in 130 cases, or 52 per cent. In the case of the other 120, or 48 per cent., no reaction for formaldehyde was obtained. As a result of this work L'Espérance comes to the following conclusions: "(1) Formaldehyde appears in the urine in only 52 per cent. of patients taking urotropin; (2) the reaction of the urine is of no importance; (3) alkalies taken with, or in combination with, urotropin have no effect on excretion; (4) duration of excretion of formaldehyde is about four to six hours; (5) increase of dosage does not affect excretion in negative urines; (6) urotropin is practically symptomless in an average dose; (7) the urine of all patients taking urotropin should be tested for formaldehyde; (8) patients not excreting formaldehyde are symptomless regardless of the amount of urotropin taken." To this inability of the kidneys of some patients to decompose the drug is attributed the varying results obtained from its use as a therapeutic agent.

K.

Salvarsan in Leprosy.—Wellman (*New York Med. Journ.*, November 16th, 1912) records the result of his treatment by salvarsan of five patients suffering from leprosy. He found that clinical improvement resulted in four out of the five patients treated, while the other case ended fatally from the result of accidental burns before the observations were completed. The two patients in whom the disease was the least advanced showed the best results. Two other patients treated with injections of normal saline were used as controls; one of these remained unchanged in condition and the other grew steadily worse and finally died. Wellman concludes that where the patient is not too weakened from the disease salvarsan may be administered without harm. Some improvement, especially in early cases, may be expected, but there is no evidence that such effect of the drug is in any way specific or permanent. Arsenic has long been employed in leprosy, "and we have no evidence that salvarsan is superior in its action to the other forms of arsenic which have been used by previous observers." K.

Typhoid Pleurisy.—Finley (*Canadian Med. Assoc. Journ.*, September, 1912) records the results of his investigations of pleurisy occurring in the course of typhoid fever. He finds that nineteen cases occurred at the Montreal General Hospital among twenty-one hundred cases of typhoid fever treated there from 1897 to June 1912. The incidence of pleurisy varies considerably in different epidemics of typhoid and in different localities. The pleurisy usually develops towards the middle or latter part of the fever, but it is sometimes found at the onset or after defervescence. In the cases examined the average period of onset was the 25th day, the two earliest cases beginning on the first and fourth days, and the two latest on the 30th and 96th days. In only nine of the cases was the quantity of fluid sufficient to warrant its removal, and of these in five the fluid was found to be sero-fibrinous, in two hæmorrhagic, and in two purulent. The typhoid bacilli occur in all types of effusion, and even in purulent cases may occur in pure culture. The course of typhoid pleurisy is almost invariably benign; the fluid usually remains small in amount, and is absorbed in a period of from two days to several weeks, leaving but little trace of pleural thickening and adhesions. Only one fatal case was recorded in the series. K.

Transverse Episiotomy.—Waldstein (*Samml. Klin. Vortr.*), after discussing the methods of lateral and median episiotomy, describes his method, which is said to combine the advantages of the others. If perineal rupture is imminent, or has already taken place, he makes an incision in perpendicular direction towards the raphe, passing through the skin, the subcutaneous tissue, to the perineal fascia; length and distance from the anus and vulva are varying, according to the increase required. The incision ought not to be shorter than 2 c.m., and should involve the tendinous perineal centre, where there is commonly a shallow groove. If there is no risk of perineal rupture, no further incision should be made. In the case of perineal rupture, it extends only to the transverse incision, and the condition resembles that produced by the incision. Where the perineal rupture cannot be prevented, a median incision should be made on the transverse, passing with its posterior angle through the sphincter ani, whilst—as the author suggests—the posterior surface of the wound, laid across and before the sphincter, is rather a protection to it. Waldstein has applied his method in 40 cases, out of which there were 36 primiparæ (the children showed a weight of from 3,500 to 7,000 gr.); nine cases were delivered by means of forceps. There has been but one case of perineal rupture. After delivery the wound extends but a short distance towards the vagina; its perineal portion shows a symmetrical shape and but little gaping. Transverse episiotomy combines, thus, the advantages of the other methods. The protection of the sphincter is a perfect one. It may be performed for preventive purposes without provoking permanent injury and gives the largest increase of space. N.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. and pro rata for smaller spaces. Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

THE WELFARE OF INFANCY.—GREAT NATIONAL MOVEMENT.

THEIR Majesties the King and Queen have graciously lent their patronage to the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy. The foundation of this Society is the outcome of a public meeting held last July at the Caxton Hall under the presidency of Mr. John Burns. It represents a Triple Alliance between the National Conferences on Infant Mortality, the National League for Physical Education and Improvement and its department, the Association of Infant Consultations and Schools for Mothers, and the Women's National Health Association of Ireland.

As an earnest of the important work the newly constituted society proposes to carry on, it has already arranged to hold in London a post-graduate course on the feeding and care of infants. This course will be held in London from January 6th to 16th next.

The Executive Committee is now actively engaged in organising an English-speaking Conference on Infant Mortality, which is to be held in London on August 4th and 5th next, a date which immediately precedes the International Medical Congress.

Further particulars with respect to the Association, membership in which is open to all who sympathise, or of the post-graduate course and the conference, may be obtained from Miss Halford, Secretary to the Association, 4 Tavistock Square, London, W.C.

PUZZLED (Liverpool).—An effectual remedy, if our correspondent has not tried it, is rubbing an unbroken chilblain with Ol. Terebenthinum.

DR. S.—In our opinion the matter does not call for further notice at present.

PATENT MEDICINE FINES.

FINES and costs amounting to £35 16s. were imposed at the Mansion House Court last week, on the London agent for some American vendors of patent medicines, for selling the said preparations without a licence, and without having paid the Government Stamp duty.

Q. B. (Worthington).—We will make inquiries, but our impression is that the work has been out of print for some years.

EX EQUALI.—The bond, though exacting, does not appear to us to be unreasonable, having regard to the circumstances.

THE MILK BILL.

THE following is the memorandum of the Milk and Dairies Bill which Mr. Burns, with Mr. Herbert Lewis, has introduced:—The main objects of this Bill are to provide for—

- (1) The more effective registration of dairies and dairymen;
- (2) The inspection of dairies and the examination of cows therein;
- (3) The prohibition of the supply of milk from a dairy where such a supply has caused or would be likely to cause infectious diseases, including tuberculosis;
- (4) The prevention of the sale of tuberculous milk;
- (5) The regulation of the importation of milk so as to prevent danger to public health arising therefrom;
- (6) The issue of regulations for securing the supply of pure and wholesome milk;
- (7) The establishment by local authorities in populous places of milk depots for the sale of milk specially prepared for infants.

The provisions as to registration supersede the provisions as to the registration of dairies contained in the Contagious Diseases (Animals) Acts and the orders made thereunder.

The provisions as to the inspection of dairies and the prohibition of the supply of milk are based on the provisions of the Public Health (Scotland) Act, 1897.

The clause as to the prohibition of the sale of tuberculous milk is taken from the model milk clauses, which have been incorporated in many local Acts, but the scope of the enactment is somewhat extended.

The Board of Agriculture and Fisheries propose to issue an order under the Diseases of Animals Act, 1894, dealing with

tuberculous cows, and providing for the payment of compensation in cases of slaughter by the local authority. The Treasury are prepared, subject to the assent of Parliament, to sanction the payment from the Exchequer of one-half of the net amount paid by way of compensations for a period of five years.

DR. S. A. (Herts).—Why not give a test meal in the case of suspected gastric cancer? It can, at any rate, do no harm. Considerable diminution of free hydrochloric acid is generally regarded as a point in favour of carcinoma.

M.D., L.R.C.P. (Exeter).—Carbon dioxide snow has been found very useful in the treatment of rodent ulcers of the face.

Appointments.

- BALL, W. GIRLING, F.R.C.S.Eng., Surgeon to the City of London Truss Society for the Treatment of Hernia.
- BENTHAM, Miss, Clinical Assistant to the Throat, Nose, and Ear Department at the Royal Free Hospital.
- CLEGG, SYDNEY JAMES, M.B., Ch.B., D.P.H.Manch., Assistant Medical Officer of Health to the City and County of Newcastle-upon-Tyne.
- CUNNINGHAM, J. F., F.R.C.S.Eng., Consulting Ophthalmologist to the Royal Bethlem Hospital.
- DAVIES-COLLEY, Miss ELEANOR, F.R.C.S.Eng., Surgical Registrar to the Royal Free Hospital.
- EVANS, A. H., M.D., M.S.Lond., F.R.C.S.Eng., Consulting Surgeon to the Royal Bethlem Hospital.
- FRASER, Miss, M.D., Medical Registrar to the Royal Free Hospital.
- HOWARTH, WILLIAM JAMES, M.D., Ch.B., D.P.H.Vict., Medical Officer of Health of the City of London.
- LEWIS, T. M.D., B.S.Lond., Assistant Physician to University College Hospital.
- MOLLINSON, W. M., M.C.Cantab., F.R.C.S.Eng., Consulting Aurist and Laryngologist to the Royal Bethlem Hospital.
- MORRIS, C. W., Registrar of Anesthetics at University College Hospital.
- O'FLYNN, Miss SARA, M.B., Ch.B.Edin., Clinical Assistant and Second Clinical Assistant to the Gynecological Department at the Royal Free Hospital.
- PURVIS, GEORGE CARRINGTON, M.D., B.Sc.Edin., Medical Officer of Health of Grahamstown, Cape Colony.
- STEVENS, T. G., M.D.Lond., M.R.C.P.Lond., F.R.C.S., Consulting Gynecologist to the Royal Bethlem Hospital.
- TURNER, Miss, M.B., B.S., Clinical Assistant at the Royal Free Hospital.
- HUGHES, CECIL HUGH MYDDELTON, M.B., B.S. Lond., Consulting Anæsthetist to the Royal Bethlem Hospital.

Vacancies.

- Mansfield and Mansfield Woodhouse District Hospital.—Resident House Surgeon. Salary £120 per annum, with board, residence, and washing. Applications to A. H. Limb, Secretary, Burnbrae, Mansfield.
- North Wales Counties Asylum, Denbigh.—Junior Assistant Medical Officer.—Salary £150 per annum, with furnished apartments, board, attendance, and laundry. Applications to the Medical Superintendent.
- Corporation of Newcastle-upon-Tyne.—City Hospital for Infectious Diseases.—Resident Medical Assistant.—Salary £125 per annum, with board, lodging, etc. Applications to the Medical Officer of Health, Health Department, Town Hall, Newcastle-upon-Tyne.
- Devonshire Hospital, Buxton, Derbyshire.—Assistant House Physician. Salary £100 per annum, with furnished apartments, board, and laundry. Applications to W. Stevenson, General Superintendent and Secretary.
- County Borough of Croydon.—Medical Officer of Health. Salary £600 per annum. Applications to F. C. Lloyd, Town Clerk, Town Hall, Croydon.
- Lancashire County Council.—Tuberculosis Officer. Salary £500 per annum. Applications to County Medical Officer of Health, County Offices, Preston.
- Caterham Asylum.—Third Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent at the Asylum.

Births.

- BURTON MARSHALL.—On Dec. 18th, at Manley House, Eaton, Norwich, the wife of William Burton Marshall, M.B., M.R.C.S. (née Kathleen Boraston), of a daughter.
- MILSOM.—On Dec. 15th, at 399 London Road, Thornton Heath, the wife of E. G. D. Milsom, M.R.C.S., of a daughter.
- PEREIRA.—On Dec. 19th, at 9 Duke's Avenue, Muswell Hill, the wife of Dr. Pereira, of a daughter.
- REYNOLDS.—On Dec. 16th, at Rosendale Lodge, 17 Streatham Hill, S.W., the wife of Russell J. Reynolds, M.B., B.S.Lond., L.R.C.P., M.R.C.S., of a son.

Marriages.

- CARSON—WILLIS.—On Dec. 19th, at All Saints, Harston, Cambridgehire, Herbert William Carson, F.R.C.S., of 111 Harley Street, son of James Hamilton Carson, Esq., to Mary, daughter of Ducan Willis, Esq., of Wallasey, Cheshire.

Deaths.

- TREMEARNE.—On Nov. 14th, at Toorak, Melbourne, Australia, from heart failure, John Tremearne, M.R.C.S., J.P., only son of the late J. N. Tremearne, of St. Ives, Cornwall.

PREVENTABLE CANCER:

A STATISTICAL RESEARCH.

By ROLLO RUSSELL.

The volume deals with statistics, rates, and incidence of the malady in many lands, and with habits on which it seems to depend. A close examination is made of its recorded increase during the last 50 years, and much evidence is adduced to account for this, and for the increase of other fatal diseases of civilisation, which are shown to be largely preventable.

London: Longmans, Green & Co., 39 Paternoster Row, E.C.

By FREDERICK J. McCANN, M.D. Edin., F.R.C.S. Eng.,
Samaritan Free Hospital for Women, London, N.W.

CANCER OF THE WOMB:

ITS SYMPTOMS, DIAGNOSIS, PROGNOSIS AND TREATMENT.

Fully Illustrated. 20s. net.

LIVERPOOL MEDICO-CHIRURGICAL JOURNAL.—"Cancer of the Womb, by F. J. McCann, is a book that can be recommended alike to the general practitioner and the specialist. Written in a fluent manner, it embodies the ripe experience of a renowned operator, trained observer, and patient investigator."

EDINBURGH MEDICAL JOURNAL.—"This book is one of very great merit; it will be read with interest both by the specialist and general practitioner as an authoritative exposition of the important subject with which it deals."

PRACTITIONER.—"Dr. McCann has produced a valuable work which deserves to be widely known."

ST. BARTHOLOMEW'S HOSPITAL JOURNAL.—"The plates are excellent. This is a book we can thoroughly recommend."

London: Henry Frowde and Hodder and Stoughton.

By W. ARBUTHNOT LANE, M.S.

Cleft Palate and Hare-Lip.

New Edition, in large clear type, demy 4to, 5s.

"Mr. Lane makes out a clear case for early and almost immediate operation. To sum up: Mr. Lane has absolutely proved his contention, and rendered it quite clear that early operation is the right course on every ground developmental and otherwise; and, further that delay in performing staphylorrhaphy until the third or sixth year is fraught with most harmful results, and should not be permitted."
—British Medical Journal, Jan. 27th, 1906.

- Ditto Binaural folding (Fig. F.) 13/6

COPIES OF UNSOLICITED TESTIMONIALS.

Dear Sirs,—“I find that most certainly the chest sounds are rendered clearer and more distinct by your 'Phonophore' than by any stethoscope I have used during over 30 years' work.”—Yours, F.R.C.S.

Dear Sirs,—“I have found your 'Phonophore' by far the best stethoscope I have ever used.”—Faithfully Yours.

Extract from the "British Medical Journal," Oct. 28th, 1911.—“Some years ago Messrs. Arnold & Sons, of Giltspur-street, E.C., brought out a stethoscope which they named the 'Phonophore.' Its construction secured a considerably increased volume of sound, and the appliance gained favour among those dissatisfied on general grounds with ordinary stethoscopes, or whose needs, owing to some lack of aural acuity, were not adequately met thereby. Of this appliance the same firm has recently brought out a modification in which the bell-like attachment constituting the chest-piece is provided with two sound tubes instead of one. These tubes are continued upwards, the sound thus being conveyed to each ear direct from the collecting chamber. Each ear, therefore, receives the same amount of sound, although the same amount of sound may not be perceived if there is any difference in the hearing power of the two ears. The gross volume of sound is also greater than supplied even by the original 'Phonophore.' This modification of the 'Phonophore' is worth examination by anyone interested in stethoscopy.”

INNSBRUCK (AUSTRIA).

SUMMER AND WINTER RESORT.

INNSBRUCK is the Capital of the Tyrol, in the centre of the Alps, and most beautifully situated; sheltered from north and open to the southern balmy Italian winds, it is favoured with a remarkable equality of temperature.

The Hotel Tyrol offers every comfort; newly enlarged Apartments with Bath, 2 Lifts, Electric Light, Hot Water Heating, Absolutely Fireproof. System, Hennebique. Large Garden. Lawn Tennis, Motor Car Shelter.

Illustrated pamphlets of Innsbruck sent on application.

CARL LANDSEE, Proprietor.

NORDRACH in WALES SANATORIUM

(PENDYFFRYN HALL).

FOR THE TREATMENT OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.

One of the first Sanatoria opened in the United Kingdom to carry out the Treatment of Consumption as practised at Nordrach and a "Preventorium" for suspected cases. Over 100 acres of private woods and grounds. Carefully graduated walks rise through pines, gorse, heather, to a height of over 1,000 feet above sea level, commanding extensive views of both sea and mountains, sheltered from E. and N.E. winds. Climate mild and bracing. Small rainfall. Large average of sunshine. Rooms heated by hot-water radiators. Electric light.

Resident Physician: GEORGE MAGILL DOBSON, B.A., M.B., B.Ch. For particulars apply to the SECRETARY, Nordrach in Wales, Penmaenmawr, N. Wales. Telegraphic Address: Pedyffryn, Penmaenmawr. National Telephone: No. 20 Penmaenmawr. Station Penmaenmawr.

PECKHAM HOUSE

Candidates are invited to send in their applications, addressed to the Secretary, with copies of only three testimonials written specially for the purpose, on or before 12 o'clock on Tuesday, the 23rd July, 1912. The appointment is made for six months. Salary £30, washing allowance £2 10s., and board and residence in the Hospital. Candidates must be unmarried, and possess a legal qualification to practise. They will be required to attend before the Joint Committees at their meeting on Wednesday, the 24th July, 1912, at 4.30 p.m., precisely. Forms of application to be obtained from the Secretary.

By order of the Committee of Management,

STEWART JOHNSON,

24th June, 1912.

Secretary.

MEDICAL LOCUM TENENS.

Gentlemen requiring a Locum Tenens would act advisedly by communicating with more than one applicant, and selecting the most suitable.

Subscribers placed on Register free of charge. Non-Subscribers charged a nominal fee to merely cover expenses.

It is particularly requested that all appointments will be duly notified to the Registrar.

Please address as follows: X 21, or A 22 (as the case may be), 18 Nassau Street, Dublin.

POOR-LAW MEDICAL OFFICERS' LOCUM TENENS.—Medical Officers seeking temporary substitutes, or practitioners willing to act as such, are requested to make application to the Locum Tenens' Registrar, Dublin Office of THE MEDICAL PRESS, 18 Nassau Street, Dublin.

SAVORY & MOORE'S PEPTONISED MILK PREPARATIONS

Savory & Moore's Peptonised Milk Preparations include Cocoa and Milk, Coffee and Milk, condensed Peptonised Milk and Milk Chocolate. They have the advantage of being highly nourishing and extremely easy of digestion. They are thus especially useful in all cases where ordinary nourishment cannot be taken, whether through illness or digestive weakness, and they are very easily prepared, as hot water only is needed.

TESTIMONY

"Your sample tin of Peptonised Cocoa and Milk led me to try this preparation in a case of gastric ulcer. I have pleasure in stating that it was borne by the patient without the slightest pain or inconvenience, when other cocas which I tried could not be tolerated." F.R.C.S.

Nurse H. has found Savory and Moore's Peptonised Cocoa and Milk most satisfactory in the case of a delicate child suffering from gastric catarrh, also in a bad case of colotomy. Nurse H. wishes to state she takes it herself twice a day, and finds it suits her better than any other cocoa.

"I have been compelled to abstain from taking tea, coffee, and various kinds of cocoa now for over eight months. I can truly say that your Cocoa and Milk has simply worked wonders with me. I have always been able to retain it, and have found it most soothing and satisfying, and of the greatest assistance in promoting sleep of which I stood in need."

"I have had during the past six weeks ample proof of the excellent qualities of your Peptonised Milk Preparations. My patient has had a most severe and acute attack of Gastritis, and the first thing she was able to take (after a fortnight's artificial feeding) was some of your Peptonised Milk. This has been continued with until now she is able to take light food. I cannot too highly recommend the milk."

"Our youngest, born prematurely, weighed under 3½ lbs., and neither the doctor nor the nurse entertained the slightest hope of its living. For over a fortnight it was fed, or tried to be, on milk peptonised by powders. As neither my wife nor I was satisfied with the non-progress I consulted —, who said that the only chance was with your Peptonised Milk. A trial was at once made, and although we scarcely thought the child would last out the tin, I am pleased to say that he has steadily increased in weight, size and intelligence, a progress which the doctor states is marvellous. Whilst the child can now take stronger food he still has some of your Peptonised Milk with each meal."

COCOA AND MILK

The Cocoa and Milk is made from specially selected Cocoa and pure, sterilised country milk, both of which undergo a special peptonising process: It is highly nourishing, of delicious flavour, and can be taken and assimilated even by those who are quite unable to take cocoa in the ordinary form.

The Cocoa and Milk is especially suitable for Invalids, Convalescents, and all whose digestive organs have been weakened by illness, overwork, study, or other debilitating causes. In cases of GASTRITIS and GASTRIC ULCER it has proved highly successful. It is also very beneficial in NERVOUS CASES, and it may be taken at night without the least fear of causing digestive disturbance.

It requires only the addition of hot water, and can thus be prepared in a moment at any hour of the day or night.

COFFEE AND MILK

This is a similar preparation, in which Coffee takes the place of Cocoa. It is equally easy of digestion, and much appreciated by those who enjoy the fragrant aroma of freshly roasted coffee. It forms an admirable non-alcoholic stimulant, and its action on the brain tissues as a restorative is highly beneficial.

PEPTONISED MILK

It is practically impossible to prepare peptonised milk in the sick room with any degree of certainty as to uniform results. In Savory & Moore's factory the various operations are carried out by a highly skilled and specially trained staff. The result is that their Peptonised milk is a uniform product of the highest quality which may be absolutely relied upon.

Savory & Moore's Peptonised Milk is of the greatest value as a food in all cases of INFANTILE MALNUTRITION, also in cases of FEVER and WASTING DISEASE, whether in children or adults. It is retained even when no other kind of food can be taken, and by its nutrient qualities enables the patient to assimilate sufficient nourishment to successfully combat disease. In many cases it has been the means of saving life, especially among infants.

The Peptonised Milk is absolutely sterile, and free from preservatives other than pure sugar. Dilution with hot or cold water, as directed, renders it ready for immediate use.

SAMPLES ON APPLICATION.

Samples of any of the above preparations, together with an illustrated Booklet describing Savory & Moore's Milk Factory, will gladly be sent, post free, to Members of the Medical Profession on request. Address—

SAVORY & MOORE, Ltd., Chemists to THE KING,
143 New Bond Street, London.
